Part-I

Design of Roads & Pavements

1 INTRODUCTION

1.1 General

Detailed ground reconnaissance surveys were undertaken which included various features along the existing alignment such as land use pattern along ROW, Topographical features of the area, identification of possible improvements in existing alignment, traffic pattern and identification of traffic homogeneous links, drainage system etc. The data and information obtained from the reconnaissance surveys was accordingly compiled and presented in Report.

The design of the project road includes following design components:

- Analysis of present traffic and future projections;
- Analysis of existing pavement structure and its residual strength;
- Determination of requirements for the new pavement including overlay over the design period;
- Determination of adequacy of the CD structures;
- Review of existing condition of existing structures;
- Review of the road's geometry (horizontal as well as vertical) and measures for improvement;
- Determination of adequacy of intersections and measures for improvement; and
- Road safety aspects through provision of traffic control devices, roadside furniture and project facilities.

1.2 Project Description

Project Road (Km. 0/000 to 8/415) commencing from Chainage 0/000 (Latitude: 25°58'58.65"N & Longitude- 90°46'56.20"E) at Dudhnoi passes through Thekashu Town, Damra Pat Para and terminates at Chainage 8/415 (Latitude- 25°54'33.23"N & Longitude- 90°46'28.20"E) at Dainadubi Design Length-8.415 km. The Project section is part of NH-217. Project road lies in Goalpara district in the state of Assam.

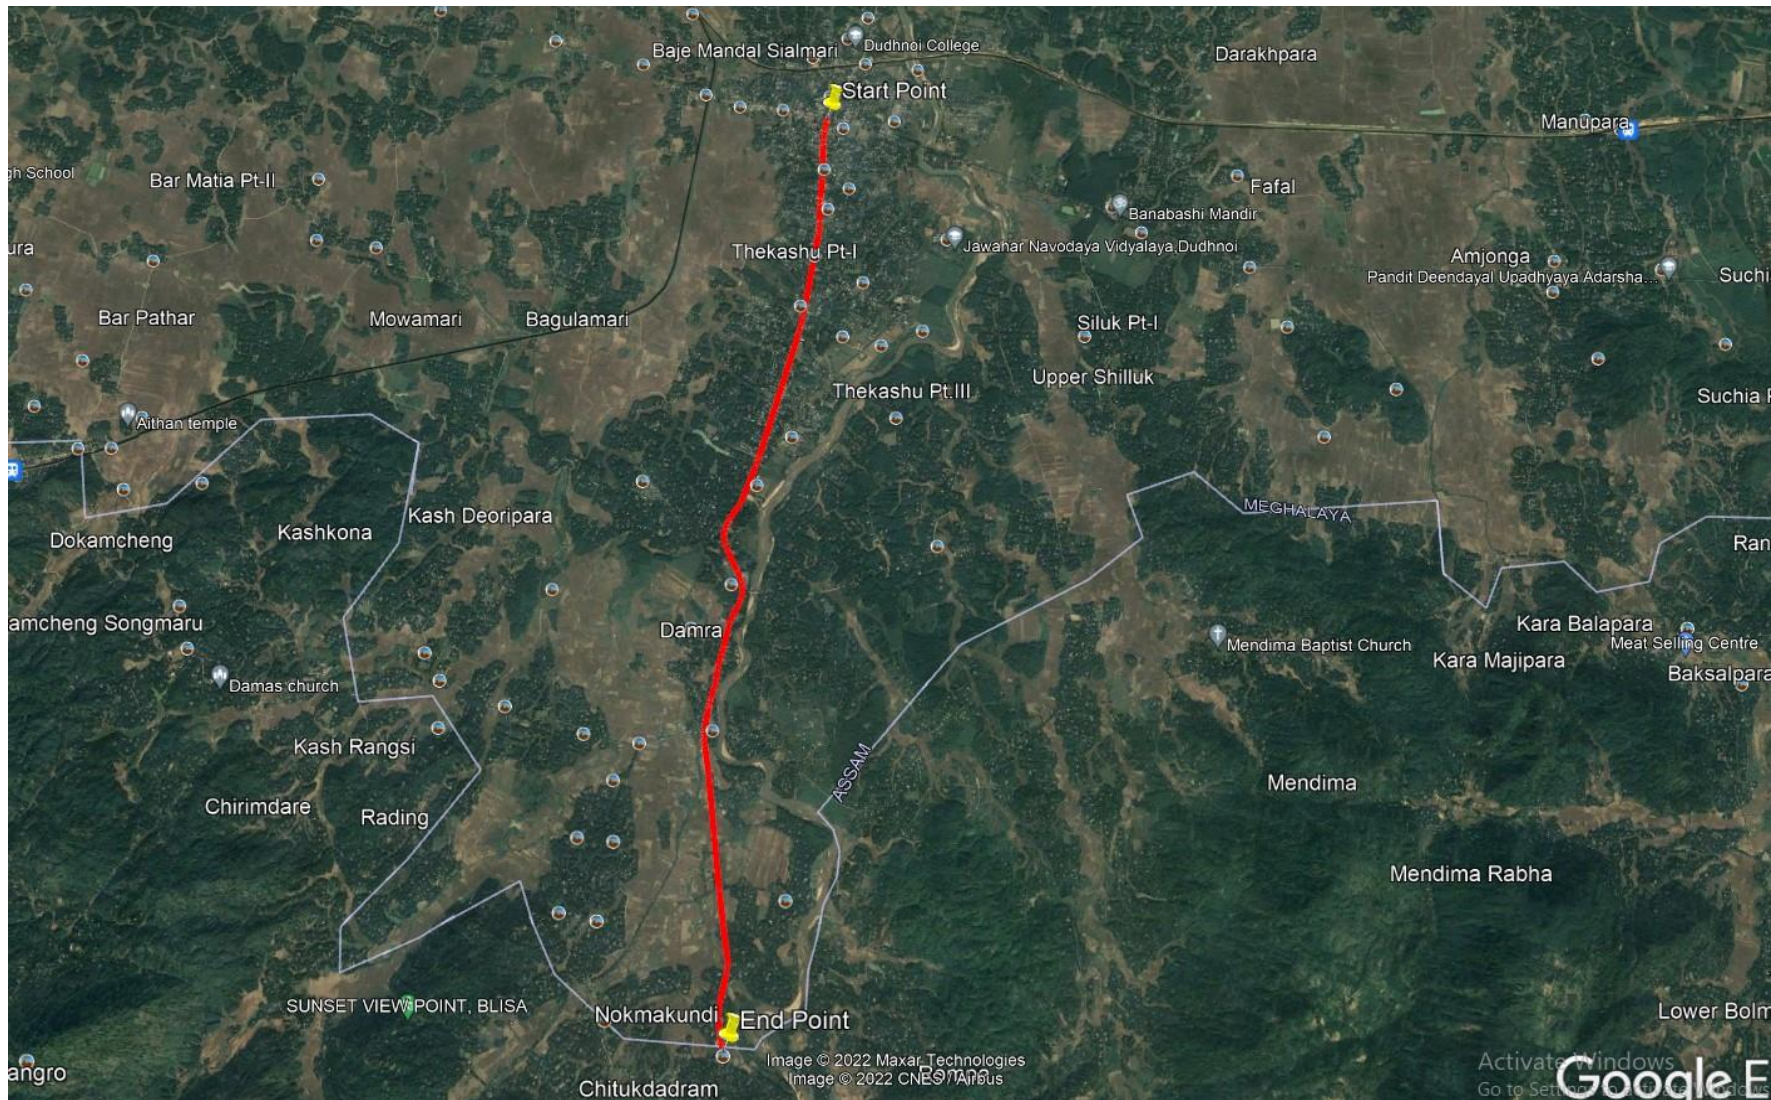

Figure 1.1: Project Road in show image below:

1.3 Design Considerations

The project design comprises geometric design i.e., the horizontal alignment and the vertical profile, and the design of appurtenances and structures, traffic control devices, roadside furniture and other project facilities. The design standard/ practices proposed to be adopted for structure design are given in Chapter 8 and 9. The geometric design consists of the below mentioned features.

- Design of horizontal alignment, vertical alignment, intersections and other features for upgrading the existing lanes to required 2-lane with/without paved shoulder configuration by widening including realignment where required;
- Minimizing shifting/acquisition avoiding obstructions or constraints like trees, utilities and structures as far as possible without affecting safety;
- The geometric design is based on available right of way (ROW) and shall conform to the standards, set out as minimum, as far as possible safety mitigation measures to be provided wherever desirable design standards cannot be achieved;
- Wherever the existing road geometrics are deficient, due importance to improvement of these sections to meet the standards subject to land constraints;
- The uniformity of design standards is maintained throughout the length of the Project Road, to the extent practical with due consideration to safety;
- Correction of any deficiencies in the vertical profile in respect of grades layout and sight distance to meet the minimum requirements;
- Design of road side appurtenances and project facilities in accordance with relevant codes of IRC or other international standards;
- The design of cross drainage works in accordance with the relevant IRC Codes and considers the location of the cross drainage (CD) works, bridges and other structures.

Site Specific:

- The project road passes through plain and rolling terrain having villages and towns along the road. Considering the physical condition and cost effectiveness, the improvement proposals are conceived and developed under following standards:
- The desirable standards which could be adopted as a rule; and
- The minimum standards, which could be accepted for difficult stretches where application of the desirable standards, would lead to exorbitant costs.
- Accordingly, design standards for geometric elements would be considered under "desirable" and "minimum" categories. The proposed standards have to be consistent with and fall within the parameters recommended in the related standards of the Indian Roads congress.

1.4 Codes and Specifications for Road Design and Safety

The highway design is based on the IRC Codes and publications shown in Table 1.1 and is in conformity with requirements set forth in MORT&H Specifications for Road and Bridge Works, Fifth Revision.

All Materials, works and construction operations shall conform to the Guidelines for the Alignment Survey and Geometric Design of Hill Roads (IRC:52-2019) and Manual of

Specifications and Standards for Two-Laning of Highways with paved shoulder (IRC: SP:73-2018), referred to as the Manual and Indian Road Congress (IRC) Codes and Standards and MORTH Specifications for Road and Bridge Works.

Where the aforesaid Manuals, guidelines, codes, standards and specifications are silent on any aspect, Good Industry Practice shall be adopted to the satisfaction of the Authority's Engineer.

Table 1.2: Design Codes / Specifications

Sr. No.	Description	Design Code
1.	Geometric Designs & standards	IRC:38-1988 Guidelines for design of horizontal curves for Highways
		IRC: SP-23-1983 – Vertical curves for Highways
		IRC:39-1986- Standards for Road Rail Level Crossings
		IRC:64-1990– Guidelines for Capacity of Roads in Rural Areas
		IRC:66-1976 – Recommended Practice for Sight Distance on Rural Highways
		IRC:73-1980– Geometric Design Standards for Rural (Nonurban) Highways
		IRC:75-2015 – Guidelines for the Design of High Embankments (First Revision)
		IRC:86-2018 – Geometric Design Standards for Urban Roads and Streets (First Revision)
		IRC:106-1990– Guidelines for Capacity of Urban Roads in Plain Areas
2.	Design of Pavement	IRC:37-2018 – Guidelines for Design of Flexible Pavements" (Fourth Revision)
		IRC:58-2015 – Guidelines for the Design of Plain Jointed Rigid Pavements for Highways (Fourth Revision)
		IRC:8-1997 – Guidelines for Strengthening of Flexible Road Pavements Using Benkelman Beam Deflection Technique (First Revision)
3.	Junctions/Intersections/ interchanges	IRC:65-2017- Guidelines for Planning and Design of Roundabouts (First Revision)
		IRC:92-2017 - Guidelines for Design of Interchanges in Urban Areas (First Revision)
		IRC: SP:41-1997 – Guideline for Type Designs for Check Barriers (First Revision)
4.	Kilometer stones, 200m stones and boundary pillar	IRC:81 – Type Design for Highway kilometer stones
		IRC:26-1967 - Type Design for 200-Metre Stones
		IRC:25-1967 - Type Designs for Boundary Stones
5.	Traffic Signs	IRC:67-2012 – Code of Practice for Road Signs (Third Revision)
		IRC:79-2019– Recommended Practice for Road Delineators (First Revision)
		IRC: SP:31 – Road Traffic signs
6.	Road Markings	IRC:35-2015– Code of Practice for Road Markings (Second Revision)
7.	Ancillary Works	IRC:80-1981 – Type Designs for Pick-up Bus Stops on Rural (i.e., Non-Urban) Highways
		IRC: SP: 12-2015– Guidelines for Parking Facilities in Urban Roads" (First Revision)
8.	Drainage	IRC: SP:42-2014 – Guidelines on Road Drainage (First Revision)
		IRC: SP:50-2013 – Guidelines on Urban Drainage
9.	Safety Measures	IRC:103-2014 – Guidelines on Tree Plantation along Rural Roads
		IRC: SP:44-1996– Highway Safety Code
		IRC: SP:55-2014 – Guidelines on Traffic Management in Work Zones" (First Revision)

1.5 Codes and Specifications of Bridge Design

The following codes and publications (latest editions) have been used for the design of bridge components including approaches:

Table 1.3: Codes and Publications used for the Design

IRC Code	Description and name of Code
IRC: 5-2015	Standard Specification and code of Practice for Road bridges, Section 1 – General Features of Design (Eighth Revision)
IRC: 6-2017	Standard specifications and code of practice for Road bridges (Section: II) Loads and Stresses Loads and Loads combinations (Seventh Revision)
IRC: 112 – 2011	Code of practice for concrete road bridges
IRC: SP:13 – 2004	Guidelines for the design of small bridges and culverts
IRC: 78-2014	Standard Specification and code of Practice for Road bridges, Section VII –Foundation and Substructure (Second Revision)
IRC: 83-2015 (Part I)	Standard Specifications and Code of Practice for Road Bridges, Section IX Bearings, Part I: Roller & Rocker Bearings (Second Revision)
IRC: 83-2018 (Part II)	Standard Specifications and Code of Practice for Road Bridges, Section IX – Bearings (Elastomeric Bearings), Part II (Second Revision)
IRC: 89 -2019	Guidelines for Design and Construction of River Training & Control Works for Road Bridges (Second Revision)
IRC: SP:35 -1990	Guidelines for inspection and Maintenance of Bridges
IRC: SP: 40 – 2019	Guidelines on Repair, Strengthening and Rehabilitation of Concrete Bridges (First Revision)
IRC: SP: 73-2018	Manual of Specifications & Standards for Two Lanning of Highways with Paved Shoulder" (Second Revision)

Where IRC Codes are silent, relevant BIS codes have been followed. In case even the BIS codes are silent, sound engineering practices have been adopted.

1.6 Key Design Parameters of Road Components

The design standards are primarily based on IRC publications, MORTH Specifications and relevant international standards and industry best practice. Where the design standards are silent, the consultant has based the design on their past experience and sound engineering practices. e.g.: geometrics embankment, pavement, structures, drainage, drawings, traffic safety and materials.

- Terrain Classification**

The following terrain classification recommended by IRC:38-1988 /IRC: SP:73-2018 is proposed to be adopted:

Terrain	Cross Slope (%)
Plain	<10
Rolling	10 – 25
Mountainous	25 -60
Steep	> 60

• Design Speed

The allowed speeds are dependent on both terrain and horizontal curvature. While the project roads are in plain and rolling terrain, the roads have many horizontal curves not meeting the design speed. In view of this, the design speeds that could be achieved shall be reviewed based on the current geometry and efforts will be towards making the road safe and conforming to design standards within the constraints.

The design speed of 100 and 80 Kmph as ruling and minimum as per IRC: SP:73 of 2018 has been adopted for road falling in plain & rolling terrain.

(c) Site Specific: It is proposed to maintain a uniform design speed except in built up/ urban areas. Reduced design speed in urban areas has been adopted to enhance safety of users (both motorized/ non-motorized and other vulnerable users as pedestrians). The change in speed from rural to urban areas and vice versa shall be made in a gradual manner by introduction of traffic calming measures so that the road users become conditioned to the change gently.

Horizontal, vertical and other design parameters are detailed in subsequent sections and summary is given in Table 1.4 as follows.

Table 1.4: Design Parameters for Plain and Rolling Terrain

S. No.	Description	Details
1.	Design Speed	100 /80 Kph
2.	Lane width	3.5 m
3.	Camber (Pavement & Paved shoulder) Flexible Pavement	2.50%
4.	Camber (Pavement & Paved shoulder) Rigid Pavement	2.00%
5.	Camber (Gravel shoulder)	3.50%
6.	Kerb shyness on footpath / separator side	0.25 m
7.	Maximum super-elevation	5.00%
8.	Minimum Sight Distance	360 / 240 m
9.	Overtaking Sight Distance (ISD)	640 / 470 m
10.	Minimum radius of horizontal curve	400 / 250 m
11.	Min. vertical gradient (primarily on new/ reconstruction carriageway)	0.30%
12.	Ruling maximum vertical gradient (Mountainous/Steep)	5.0/6.0%
13.	Limiting maximum vertical gradient for short length (Mountainous/Steep)	6.0/7.0%
14.	Minimum length of vertical curve	60 m/ 50 m

2 ROAD CARRIAGEWAY AND CROSS-SECTIONS

2.1 Introduction

The project area was studied from satellite imaginaries and topographical maps (from Survey of India) to understand the terrain, environmental and social features including water bodies, forest areas, built-up areas etc. Reinforced with the information from maps, site visits were made to study and understand various site constraints, land uses, environmental sensitive features, developmental activities and presence of utilities. These were followed by detailed inventory and surveys of various road and structure features including carrying out of utility survey.

The following IRC codes and standards have been referred to for finalizing the design of cross-sectional elements.

Table 2.1: Codes Pertaining to Road Cross Sections

(i)	IRC:73-1980	Geometric Design Standards for Rural (Nonurban) Highways
(ii)	IRC:86-2018	Geometric Design Standards for Urban Roads and Streets (First Revision)
(iii)	IRC:106-1990	Guidelines for Capacity of Urban Roads in Plain Areas
(iv)	IRC:64-1990	Guidelines for Capacity of Roads in Rural Areas.
(v)	IRC: SP:73-2018	Manual of Specifications & Standards for Two Lanning of Highways with Paved Shoulder" (Second Revision)

2.2 Road Carriageway and Cross-sectional Elements

The cross-sectional elements of road comprise of:

- Right of way (ROW);
- Road carriageway;
- Width at cross drainage structures;
- Shoulders;
- Width of drainage or footpath and
- Camber or cross fall.

The above elements together constitute complete road cross section. Adoption of various elements in an appropriate manner, in accordance with IRC guidelines for safe movement of traffic is a major design requirement. These are detailed in the following sections. Details of Road inventory and pavement condition are attached in Annexure-I & II respectively.

2.3 Roadway Width (Carriageway Width)

The IRC:73-2018 lays down formation width guidelines for 2 lane carriageway configurations for Highways in plain & rolling terrain as 7.0m.

Shoulder Width:

The normal shoulder width as per IRC: SP:73-2018 shall be 2.5m on either side in roads passing through plain and rolling terrain. In open country 1.5 m paved & 1 m earthen shoulder and in built-up areas 2.5 m shoulder width is taken.

Type of Shoulder:

Type of Section	Width of shoulder (m) on either side		
	Paved	Earthen	Total
Open country with isolated built-up areas	2.5	1.5	4.0
Built-up section (2-lane section)	2.5	-	2.5
Approaches to grade separated structures	2.5	-	2.5
Approaches to bridges	2.5	1.5	4.0

Camber

As per IRC: SP:73-2018 a camber of 2.5% in straight sections of flexible pavement surface (including paved shoulder), 2.00% in rigid pavement surface (including paved shoulder) and 3.5% in the granular shoulder is recommended and same will be adopted.

Sr. No.	Pavement/Surface	Camber %
1.	Flexible	2.50
2.	Rigid	2.00
3.	Earthen Shoulder	3.50

Footpath

Nil

Site Specific

The project road is proposed new construction of 2-lane carriageway with earthen/paved shoulder. Since the road is important and considering the safety and future capacity issues, it is proposed to have the Formation width components shall comprise of as under:

For 2-lane & earthen Shoulder Configuration

Carriageway - 1 x 7.00 m = 7.00 m

Paved shoulders - 2 x 1.5 m = 3.0 m

Earthen Shoulders - 2 x 1.0 m = 2.0 m

Following would be some departures/ changes from above:

- On horizontal curves, the carriageway width is increased to account for the extra widening requirements for curvature;
- In built-up areas, the earthen shoulder will be replaced by paved blocks wherever applicable;
- At built-up sections and other locations where traffic calming measures are considered, central hatching in for virtually segregating directional traffic may be provided where enough space is available.

2.4 Right of Way (ROW)

Proposed ROW will be as per the table given below:

Design Chainage From(km)	Design Chainage To(km)	Design Length (km)	EROW as per Revenue Records (m)	PROW (m)	Remarks

3 IMPROVEMENT PROPOSALS

3.1 Formulation of Proposals

The project basically involves proposal of Alignment to 2-lane carriageway with paved shoulder with geometrics to provide a design speed of 100/80 kilometer per hour.

The two main components that comprises of improvement proposals are:

- Geometric
- Structural

The economic and traffic considerations determine and dictate the Geometric component. This component deals mainly with the visible elements of the roadway such as - horizontal and vertical alignments, sight distance considerations, cross sectional elements, lateral and vertical clearances, intersection treatment, control of access etc.

Similarly, the structural component with the invisible physical strength characteristics of the pavement and embankment aspects under the application of wheel loads, the adequacy of their durability to withstand such loads over the design period dictate the structural component.

3.2 Other Improvements

In addition to alignment proposals, other major improvement proposals include:

- Strengthening or reconstruction of existing pavement after pavement investigation
- Re-designing of major and minor junctions to IRC Standards
- Adequate drainage provision, both surface and sub-surface
- Cross-drainage structures - improvements and new
- Provision of road safety devices and road side furniture both for motorized and non- motorized users.
- New project facilities
- Landscaping and tree plantation.
- Street Lightening in Junctions and Bus shelters.

4 ALIGNMENT DESIGN

4.1 Introduction

The existing road is an intermediate / two lane and has relatively good to poor geometry. The road has been proposed to be improved for design speed of 100/80 kmph wherever possible due to land width restrictions.

The following IRC codes and standards have been referred to for finalizing the alignment.

Table 4.1: Codes Pertaining to Alignment Design

(i)	IRC:73	Geometric Design Standards for Rural (Non-Urban)
(ii)	IRC:86	Geometric Design Standards for Urban Roads in Plains
(iii)	IRC:106	Guidelines for Capacity of Urban Roads in Plain Areas
(iv)	IRC:64	Guidelines for Capacity of Roads in Rural Areas.
(v)	IRC: SP:73	Manual for Two Laning of State Highways

The various alignment (horizontal and vertical) elements of any road comprise of:

- Radius of curve
- Super-elevation
- Transition length
- Extra widening
- Vertical Curve length
- Gradient

The above elements together are integral part of geometry of road. Adoption of various elements in an appropriate manner, in accordance with IRC codes for safe movement of traffic is a major design requirement and is detailed in the following sections.

4.2 Horizontal Alignment

4.2.1 General

As per the requirements of IRC: SP: 73-2018, the following guidelines were followed during the design:

- Uniformity of design standards and speed;
- Horizontal alignment to be fluent and blend well with the surrounding topography;
- Limit the adverse impact to the existing environment
- Design of horizontal alignment in consideration of the longitudinal profile and vice versa; and
- Alignment near location of bridges and their approaches integrated keeping in view the overall technical DPR and improvement proposal of bridges

The geometric design shall also be undertaken to minimize impact on trees, utilities, properties, religious places and avoid extending beyond the existing right of way (ROW).

Site Specific

The Project Road is a State Highway. ROW details in the form of boundary stones are not found at site; therefore, ROW details based on Revenue map and observed property lines are considered for the design of alignment.

The horizontal alignment has been designed in such a way that additional land requirement /acquisition is minimum (to nil) and the impact of widening is less on existing built-up areas and existing environmental and social features. The existing carriageway, structures/bridges etc. are utilized to the extent possible unless proved otherwise.

4.2.2 Design Elements

Radius of Horizontal Curves

In general, horizontal curves consist of a circular curve portion flanked by a spiral transition on both ends. These shall correspond to the ruling minimum and absolute minimum design speeds and the maximum permissible values of super-elevation as per IRC: 73:1980 guidelines.

For the roads in plain/ rolling terrain, for the design speed of 100 kmph, the radius of more than

400 m and for the design speed of 80 km/h, the radius of more than 250 m shall be provided in design for the horizontal curves and is as per IRC: SP:73/IRC:73. Wherever possible and permissible, higher radii will be adopted.

The minimum radii of horizontal curves for different terrain conditions considering a maximum super-elevation of 7% is shown in Table 4.2.

Table 4.2: Minimum Radii of Horizontal Curves (in meters)

Plain & Rolling Terrain	
Desirable Minimum	Absolute Minimum
400	250

Super Elevation

Super elevation is required for all the horizontal curves with radius less than 1800 m in order to counteract the effect of centrifugal force. As per IRC: 38-1988, super-elevation to fully counteract the centrifugal force for 75% of the design speed neglecting the lateral friction developed will be adopted in design.

The maximum super elevation allowed as 7%, however maximum adopted is 5% on the project road.

Transition Curves - Transition curves are necessary for a vehicle to have smooth entry from a straight section into a circular curve. The transition curves also improve aesthetic appearance of the road besides permitting gradual application of the super-elevation and extra widening of carriageway as may be needed at the horizontal curves.

The horizontal curves with radius of curvature < 1800 m for 100 kmph and <1100 m for 80 kmph, transition curves are provided on both ends of circular curve.

4.2.3 Site Specific

Based on above methodology, the horizontal alignment has been designed using MX Road software. The horizontal alignment details with intersection points along with radius are listed in Annexure to Volume I (Main Report).

Extra widening at curves is proposed depending upon the radii that are less than 300m.

Due to constraints in ROW, large scale easing of sub-standard curves is not feasible. Wherever, improvement of curves for design speed considerations is not possible, speed limitation has been applied along with necessary safety measures.

4.3 Vertical Alignment

4.3.1 General

The vertical alignment is proposed to provide for a smooth longitudinal profile consistent with design speed, layout of the terrain and land-use. Too frequent grade changes cause kinks and visual discontinuities in the profile. Considering this, a gap of 150m has been adopted between two grades, mainly on sections with re-construction of pavement.

The existing road profile has been followed as far as possible, where the project road improvement is limited to widening and strengthening of the existing road. In case where the existing pavement has disintegrated and in sections which are prone to submergence, reconstruction of the pavement has been proposed and the design road level have been fixed taking into consideration the HFL.

Decks of small cross-drainage structures will conform to the profile of the new road section in case of new construction / reconstruction. Where existing structures are retained, the profile of the road has been suitably adjusted to avoid loading the existing deck with overburden/surcharge.

4.3.2 Design Elements

Gradients - Grades have been selected carefully keeping in view the design speed, terrain conditions and nature of traffic on the road.

The ruling and absolute maximum longitudinal gradients are recommended by IRC: SP:73 of 2018 as 2.5% and 3.3% respectively for plain & rolling terrain. Similarly, for mountainous terrain ruling & absolute maximum gradients are 5.0% & 6.0% respectively. Profile design of existing carriageway has been done keeping in view of minimizing profile corrective course (PCC) quantity.

Minimum Gradient for Drainage - As per IRC; SP: 73:2018, on un-kerbed pavements on embankment, near level grades may be acceptable when the pavement has sufficient camber to drain the storm water laterally. However, in cut sections, or roads at ground level, or where the pavement is provided with Krebs, it is necessary to provide some gradient for efficient drainage. Recommended minimum gradient for this purpose is 0.5% if side drains are lined and 1.0%, if these are unlined.

Further, a minimum longitudinal gradient of 0.3% would be ideally adopted from drainage point of view in re-construction sections.

Vertical Curves - These are introduced for smooth transition at grade changes. There are two types:

- Summit curves or convex vertical curves or hog curves; and
- Valley curves or concave vertical curves or sag curves.

Length of these curves is controlled by sight distance requirement, but curves with greater length are aesthetically better and improves safety. Minimum lengths of vertical curves as per IRC; SP:23-1993 and adopted are shown in Table 4.3 below.

Table 4.3: Minimum Length of Vertical Curves

Design Speed (Km/h)	Maximum grade change (percent) not requiring a vertical curve	Minimum length of vertical curve (meters)
Up to 35	1.5	15
40	1.2	20
50	1.0	30
65	0.8	40
80	0.6	50
100	0.5	60

Due to changes in grade in the vertical alignment of the road, vertical curves at the intersection of the different grades will be provided in the design so as to smoothen the vertical profile resulting in easing off of the changes in the gradients for the fast-moving vehicles. Both summit curves and valley curves will be introduced as per IRC guidelines.

Length of summit curves is governed by the choice of sight distance. Length of the valley curves should be such that for night travel, the head light beam distance is equal to the stopping sight distance. The lengths of the valley curves are worked out as per the guidelines and formula given in the IRC: 73.

4.3.3 Sight Distance

As per IRC recommendations, the minimum sight distance (Stopping sight distance, SSD) is 360 m for 100 kmph and 240 m for 80 kmph and overtaking sight distance (OSD) is 640 m for 100 kmph and 470 m for 80 kmph.

4.3.4 Site Specific

The vertical profile of the existing road is having the grades which are within permissible limits as per the terrain requirements. The profile will be smoothened by providing smooth vertical curves.

The profile of new and existing carriageway alignment has been designed with reference to the existing profile. The proposed alignment has been designed with smooth gradients. The profile of the existing road has many undulations, which have also been smoothened.

The details of vertical profiles are given in the drawing, enclosed in the Drawings Volume. The given profile shows the proposed levels along the proposed center line along with the detail's super elevation, extra widening and all existing features.

	CONSULTANCY SERVICES FOR PREPARATION OF DPR FOR ECONOMIC CORRIDORS, INTER CORRIDORS AND FEEDER ROUTES TO IMPROVE THE EFFICIENCY OF FREIGHT MOVEMENT IN INDIA UNDER BHARATMALA PARIYOJNA (LOT-01) -(PKG-1B)- DUDHNOI – DAINADUBI NH-217 ROAD FROM KM 0+000 to KM 8+415, EXISTING LENGTH- 8+415 KM.	Design Report (DDPR)
--	---	----------------------

The existing road has been used to maximum extent possible. The maximum proposed road gradient is 2.5% to provide a smooth longitudinal. The height of embankment has also been raised considering the hydrological data and HFL criteria. The road is designed for intermediate sight distance.

5 JUNCTIONS/ INTERSECTIONS

5.1 General

Intersections are important element of road and at grade intersections are very common. The design scope covers improvement of existing at grade junctions and intersections. The main objective of the intersection design is to minimize the severity of potential conflicts between cars, buses, trucks, cycles and pedestrians, while facilitating the convenience, ease and comfort of people traversing the intersections.

Intersection design should be fitted closely to the operating characteristics of users. Basic elements that have been considered in intersection design are:

- Human Factors: driving habits of road users, reaction time of various road users
- Traffic Considerations
- Physical Elements: median and island provisions, land availability, traffic control devices, drainage features etc.
- Economic Factors: cost of improvements.

5.2 Basic Design Principles

Primary considerations are safety, smooth and efficient flow of traffic. Intersections are designed having regard to flow, speed, composition, distribution and future growth of traffic. Design has to be specific for each site with due regard to physical conditions of the site, the amount and cost of land. Cost of construction and the effect of proposal on the neighborhood. Allowances for space are needed to accommodate traffic signs, lighting columns where applicable, drainage, public utilities etc.

Intersections are to be designed for peak hour volumes. Estimation of future traffic and its distribution during peak hours is done on the basis of estimated traffic and by accounting form factors like new development of land, socio-economic changes etc.

The radii of intersections curves depend on the turning characteristics of design vehicles their numbers and the speed at which vehicles enter or exit the intersection area. In urban area additional conditions like restriction of right of way widths, abutting developments, pedestrian crossings, parked vehicles and high cost of land govern minimum radii at intersections. However, to ensure traffic operation on arterial streets as per IRC SP:41, the common turning radii of 4.5 to 7.3 for passenger cars and 9m to 15 m for trucks and buses are recommended. And also, in urban area if curve radii is increased, the pedestrian crossing distance increases. Since this has pedestrian safety implications, this should be kept in view while deciding on the turning radius to be provided.

In hilly and rolling terrain, site condition governs the alignment, grade of the intersection. The following are the basic principles to be given due attention during the design.

- The intersecting roads shall meet at or nearly at right angle. However, angles above 60 degrees do not warrant realignment;
- Intersection on sharp curves should be avoided because the super elevation and widening of pavement complicates the design;
- The gradient of intersecting highways should be as flat as practicable up to section that are used for storage space; and
- Grades in excess of 3 percent should, therefore, be avoided on intersections while those in excess of 6 per cent should not be allowed.
- Junctions/ Intersections should be avoided inside the horizontal curves; primarily sharp as they obstruct the sightlines/ forward visibility.

The specific intersection design depends on physical conditions of the site, such as topography, available ROW, land use, development along the intersecting roads, expected volume of through and turning traffic.

It is desirable to provide Krebs at the intersections in urban and sub-urban area. Krebs are to be of mountable type except for pedestrian refuge where these shall be non-mountable. In intersection design the possible use of traffic control devices and another road furniture is considered. The common types of traffic control devices are: road markings; road signs; reflectors/ delineators and railings.

5.3 Site Specific

The majority of the existing road junctions are formed with village and minor roads except 01-Major junctions that necessitate careful design considerations. Following Junctions/Cross Roads will be improved as per specification:

There total 30 junctions of which 1 is Major junction & 29 are Minor Junction/Cross Road. List of Junction is given in the table below:

Table 5.1: Road Junctions

Sl. No	Design Chainage (Km.)	Classification of crossroad	Type of Junction	Type of Cross Road	Side	Road Leading to	Remarks

	CONSULTANCY SERVICES FOR PREPARATION OF DPR FOR ECONOMIC CORRIDORS, INTER CORRIDORS AND FEEDER ROUTES TO IMPROVE THE EFFICIENCY OF FREIGHT MOVEMENT IN INDIA UNDER BHARATMALA PARIYOJNA (LOT-01) -(PKG-1B)- DUDHNOI – DAINADUBI NH-217 ROAD FROM KM 0+000 to KM 8+415, EXISTING LENGTH- 8+415 KM.	Design Report (DDPR)
--	---	----------------------

Achieving desired standards would require land and structures acquisition. MORT&H guidelines will be followed.

For remaining road junctions with village/ minor roads, typical standard designs as per MORTH are proposed with appropriate modifications, considering the ROW constraint and additional safety measures. Specific designs will also be produced, as necessary.

The vertical profile/ grade line of cross-roads would meet the project road without undue steep gradients with a flat section adjoining mainline; with due consideration given to land and local constraints.

6 PAVEMENTS

6.1 Introduction

Pavement design aims at determining the total thickness of the pavement structure as well as the thickness of the individual structural components for carrying the estimated traffic loading under the prevailing environmental conditions. Many design methods, from purely empirical to rigorous analytical ones are available, and these are practiced in different parts of the world. The design methods adopted in other countries may not be applicable to Indian climatic conditions. In India, the generally adopted method of design of flexible pavement is based on IRC: 37. Accordingly IRC: 37-2018 “Guidelines for the Design of Flexible Pavements (Fourth Revision)”, has been adopted and used for the current project.

6.2 Review of Design Methods for New Construction

The AASHTO and IRC methods of pavement design have been reviewed before recommending the pavement composition. However, in the perspective of such review, it is important to note that no method in practice can be considered better than the other as each method has its own inherent limitations, owing to the characteristics of materials used in construction and their complex interaction, climatic and traffic conditions. The other methods of TAC and NAASRA may not be applicable for the current project road pavement design due to limitations on fatigue failure criteria and nature of materials considered in the design criteria does not suit the project requirements and hence the same were not considered for pavement design.

6.3 AASHTO-93, Guide for Design of Pavement Structures

This method of approach is based on empirical expressions obtained from the AASHO road tests. This approach considers the „Present Serviceability Index“ (or PSI, the performance variable), „reliability“ (probability that the pavement system will perform its intended function over the design life and under the conditions encountered during the operation period), resilient modulus of sub-grade besides the constituent materials, drainage and climatic conditions.

This method gives the total required pavement composition in terms of the parameter „Structural Number“ (SN, which is represented by the sum of the product of the layer coefficient, the thickness expressed in inches and the drainage coefficient of each layer of pavement) and a procedure to arrive at the individual pavement layer thicknesses in relation to the strength characteristics of the pavement layers, defined as layer coefficients. An acceptable „serviceability“ is considered as a main design criterion in this method. The end of design life is considered in the form of a terminal PSI, which usually corresponds to a minimum acceptable riding quality.

6.4 IRC: 37 - 2018, Guidelines for the Design of Flexible Pavements

The pavement designs given in this guide are based on the results of pavement research work done in India and experience gained over the years on the performance of the designs given therein. Flexible pavement has been modelled as a three-layer structure with stresses and strains at critical locations computed using the linear elastic model FPAVE developed under the Ministry of Road Transport & Highways Research Scheme, R - 56 and further updated it with IITPAVE recently.

The pavement designs are given for sub-grade CBR values ranging from 2% to 15% for different pavement type options like Cement Treated base and Sub base, use of RAP in asphalt layer with foamed bitumen or emulsion. The pavement compositions given in the design catalogue are relevant to Indian conditions, materials and specifications. Where changes to layer thickness and specification are considered desirable from practical considerations, the guidelines recommend modifications using an analytical approach. Hence, the design has been carried out based on the procedure given in IRC: 37-2018.

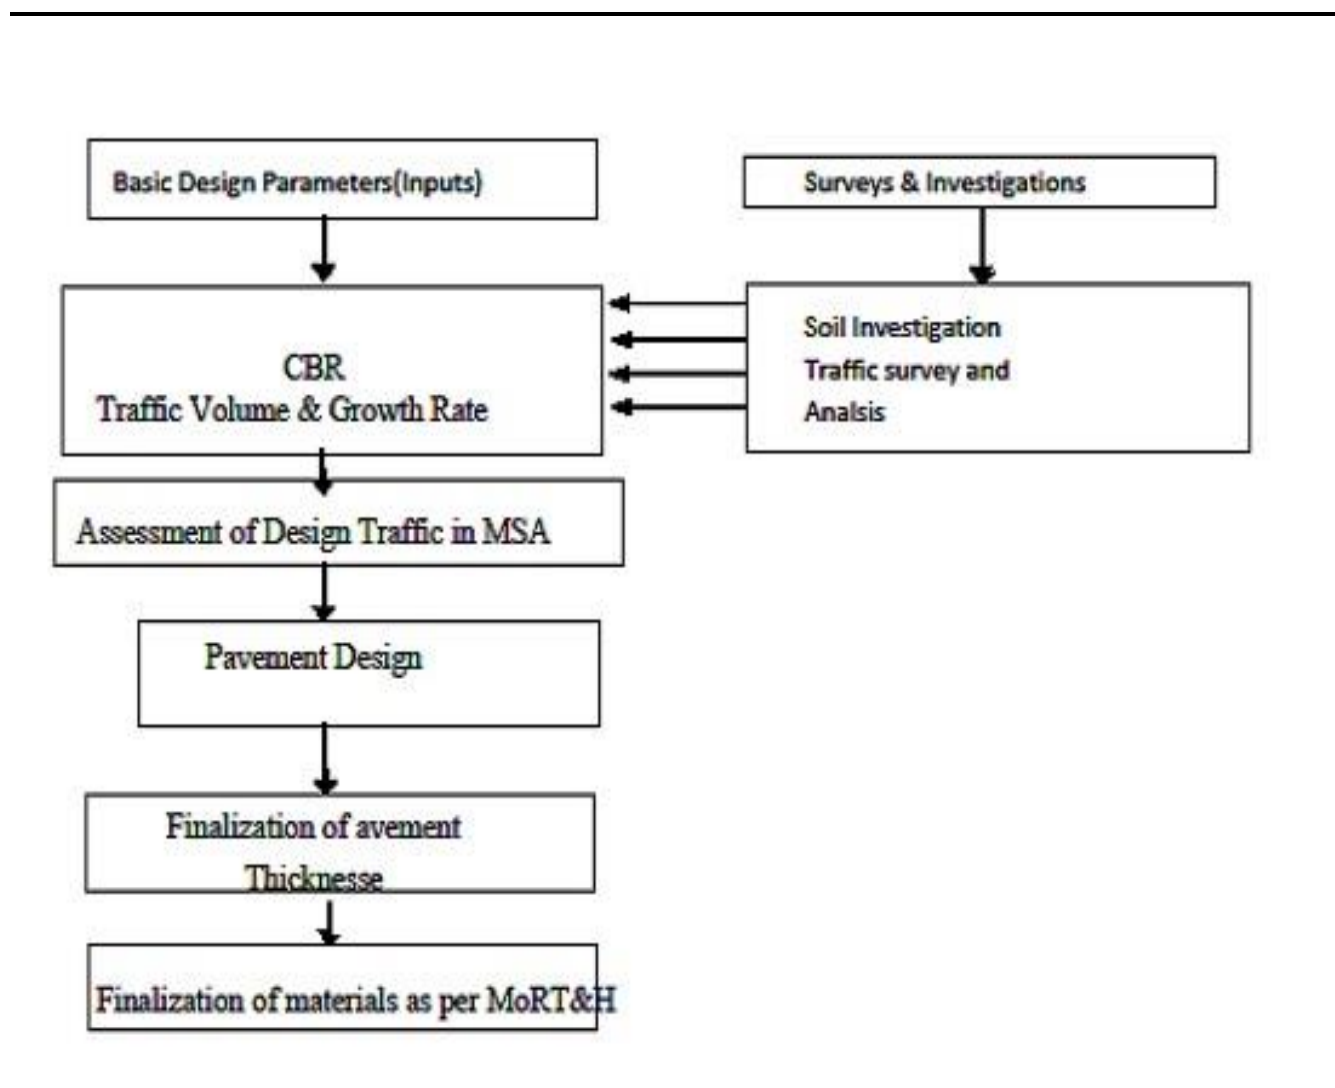

6.5 Design Methodology

The design shall be based on various design parameters as evaluated from various field and laboratory investigations, design procedures with the objective to ascertain optimal pavement structure meeting the structural requirements for the traffic and complying with the provisions of the relevant codes and guidelines. The structural requirements are:

- (i) The total thickness of the pavement and the thickness of individual layers should be designed in such a way that they are not subjected to stresses or strains exceeding those admissible in view of the material characteristics and performance factors,
- (ii) The pavement layers should be able to with stand repeated applications of wheel loads of different magnitudes under the actual conditions of sub grade, climate, drainage, and other environmental factors during the design life without causing
 - a. Excessive permanent deformation in the form of rutting and undulations;
 - b. Cracking of bituminous layers; and
 - c. Other structural and functional deficiencies such as potholes
- (iii) Ensure structural and functional performance under varied conditions and factors affecting the performance of the road i.e., soil type, traffic, environment, etc.

Pavement design guidelines given in IRC:37-2018 adopts are based on the Analytical method which is believed to have been developed based on performance of existing designs and using analytical approach (to limit the vertical compressive strain at the top of sub grade and horizontal tensile strain at bottom of bituminous layer adopting linear elastic model). Flow chart showing the various steps involved in the design process is given in Figure 6.1 below.

Figure 6.1: Flow Chart Showing the Pavement Design Methodology

6.6 Evaluation of Pavement Design Parameters

6.6.1 Design Life

Design life is the time from original construction to a terminal condition for a pavement structure. Structural design is carried to withstand the pavement for a traffic loading encountered over the design life. IRC: 37-2018 suggests design life of 20 years for the flexible pavements and accordingly, design period of 20 years has been considered for the design of pavement.

6.6.2 Traffic Volumes

A detailed traffic surveys and analysis for the project roads have been conducted in the year 2018, hereinafter called, “Base Year”. Detailed traffic projections over

the design life and growth rates obtained for different types of vehicles are discussed in traffic chapter. For the purpose of pavement design, commercial vehicles of gross vehicle weight more than 3 ton have been considered. Such vehicles consisted of buses, LCVs, 2 axle trucks, 3 axle trucks and multi axle trucks.

From total projected base year AADT and estimated traffic growth rates, vehicle category-wise traffic volume projections have been made for various design periods. Table 6.1 gives the total projected base year (2019) traffic volumes in terms of AADT for each of the identified traffic homogeneous section and has been used for the estimation of design traffic in terms of MSA for pavement design.

Table 6.1 AADT Traffic Summary

Vehicle Category	("At km 3+500 (Near Damra A.S.A. Playground))	
	AADT (Nos)	AADT (PCU)
Two Wheeler	1753	877
Three Wheeler/ Auto	1139	1139
Car/Jeep/Van/ Taxi	1076	1076
Mini Bus	70	105
Bus	21	63
LCV	255	383
2-Axle Truck	70	209
3-Axle Truck	5	16
M-Axle Truck	11	48
Tractor With Trailer	34	154
Tractor Without Trailer	2	2
Total Fast Moving Vehicles(FMV)	4435	4071
Cycle	926	463
Cycle Rickshaw	1	1
Hand Cart	10	29
Bullock Cart	1	9
Horse Cart	0	0
Total Slow Moving Vehicles(SMV)	938	503
Total	5373	4573
CVPD	432	—
Tollable Traffic	1508	1899

6.6.3 Projected Traffic

The total projected traffic is the sum of generated traffic, induced and diverted traffic. The total projected traffic on to the project road has been presented in Table 6.2 below.

Table 6.2: Traffic Forecasts

6.6.4 Vehicle Damage Factors

Project specific comprehensive axle load surveys were conducted for each the project road to estimate the loading behavior of commercial vehicles plying on the project road. The detailed analysis and raw data of axle loads collected from site from axle load surveys is provided in Chapter-3, Surveys & Investigations of this report. The summary of VDFs is given in Table 6.2 below.

Table 6.3: Vehicle Damage Factors

TYPE OF VEHICLES	VDF		
	UP	DOWN	MAX
M-Axle	8.655	4.084	8.655
3-Axle Truck	5.497	3.706	5.497
2-Axle Truck	2.619	3.738	3.738
Bus	0.334	0.741	0.741
Mini Bus	0.021	0.085	0.085
LCV	0.012	0.019	0.019

6.6.5 Strength of Sub grade

The strength of sub-grade in terms of California Bearing Ratio (CBR) is required for the design of new flexible pavement as per IRC: 37-2018. Where there is difference between the CBRs of the select sub grade and embankment soils, the design should be based on effective CBR. As new pavement will be constructed with select sub grade, the effective CBR will govern the design. Top

200mm of the embankment layer is also proposed to be constructed with select SG soil of the same CBR value to get higher effective CBR of the SG. Consultants have explored the potential sources of borrow areas with minimal leads from the project road by Inquiring with local inhabitants regarding the availability of land pieces for soil extraction enabled multitude of soil borrow areas identification. The details of materials investigation and testing have been briefly covered in the surveys and Investigations chapter. In general, Soil borrow areas will have to be rented or purchased, for which negotiations with private owner(s) may be required during execution phase of the project.

As per MoRT&H clause 305, the borrow earth material shall satisfy the following engineering properties for use in the sub grade and embankment.

Filled in	Free Swell Index	LL	PI	MDD(g/cc)
Sub grade	≤50%	50%	25%	≥1.75
Embankment	≤50%	50%	25%	≥1.52 up to 3m height ≥1.60 more than 3m height

6.6.7 Evaluation of Design Traffic (MSA) for Pavement Design

Base year traffic (vehicle category-wise & in terms of AADT), traffic growth rates, design life (in terms of number of years) and vehicle damage factors are required to estimate the design traffic in terms of equivalent standard axles. The following data have been considered to arrive at the design traffic (MSA).

- Base year - 2018
- Traffic opening year - 2024 (assumed)
- Design Life - 20 years (i.e., from year 2024 to year 2043, inclusive of both the years)
- Traffic growth rates adopted from project traffic studies conducted but minimum 5%.
- Vehicle damage factor - as listed above.

For flexible pavements, the percentage of vehicles in heaviest loaded lane can be determined as per IRC: 37-2018 guidelines given below:

Type of facility	Lane distribution factor
2- lane single carriageway	50 % of total two directional
2-lane Dual Carriageway	75% of total one directional

With the base year traffic in terms of CVPD, annual growth rate of each of commercial vehicle over the design period, design traffic in terms of MSA over the design life can be estimated using the following formula.

$$N = \frac{365 \times [(1 + r)^n - 1]}{r} \times A \times D \times F$$

Where, N = Cumulative number of standard axles to be catered

A = Initial number commercial vehicles per day in the year when the road is operational

r = Annual rate of growth of commercial traffic

n = Design period in years

D = Lane distribution factor, given below

F = Vehicle Damage Factor

The summary of MSA is given in Table 6.3 below.

Table 6.4: Design MSA for the Project Roads

Sr. No	Station	Calculated MSA on year 2043 (20 th Design Year)
1	At km 3+500 (Near Damra A.S.A. Playground)	3.14

Details Traffic data (AADT, Traffic-projection & MSA Calculation) attached in Annexure-VI, VII & VIII.

6.6.8 Design of Pavement Structure as per IRC: 37-2018

As per Pavement Design Catalogue of IRC 37: 2018, flexible pavement thickness required is as follows:

The pavement structure has been worked out for all the homogeneous sections of the project road and is given in Table 6.4 below.

Table 6.5: Pavement Composition and Thickness for new construction.

Section	Design Period (Years)	Calculated MSA	Adopted MSA	CBR (%)	Pavement Crust Compositions				
					BC (mm)	DBM (mm)	WMM (mm)	CTSB (mm)	Total (mm)
Dudhnoi-Dainadubi	20	3.14	20	7	30	50	150	200	430

The calculated pavement thicknesses have been checked by IIT-PAVE software. As per IRC-37-2018, VG-40 is to be used in this case since design MSA is 20. Analysis & result of IIT-PAVE have been attached in Annexure-V.

6.6.7 Binder Selection for BC and DBM

The long-term satisfactory performance of pavements is influenced by the pavement ingredient materials and their properties. In bituminous pavements besides stone aggregates, the bituminous binder is the key ingredient which makes its selection an important task. It is the costliest component of the bituminous mix. In India, the bitumen grading was practiced until 1992 on the basis of penetration test, which is conducted at a temperature of 25°C, and 60/70 penetration grade bitumen, was widely used. The most common problem in the performance of bituminous mix with this binder was rutting during hot summer. The bitumen becomes soft in the 60 to 70°C temperature range (typical road surface temperature on a hot summer day) and starts to push and shove under loaded truck tires leading to rutting and corrugations in the wheel tracks of the roadway. To minimize this problem, the BIS switched over from Penetration based grading system (IS: 73-1992) to Viscosity based grading system (IS: 73-2006). This standard has been further revised and the current standard is: 73- 2013 (Paving Bitumen-Specifications).

The MORTH Specifications for Road and Bridge Works 5th revision allows use of both viscosity grade bitumen and modified bitumen.

The modified bitumen is not recommended due to following reasons:

- The modified bitumen requires the use of appropriate industrial process and plant with high shear mill, and testing facilities to achieve stable and homogeneous mix. Transportation tanks and storage tanks need to be insulated and equipped with effective heating system and circulation/ agitating device to maintain the specified temperature, homogeneity and viscosity of bitumen during transit and storage. Moreover, CRMB must be used as soon as possible since its quality can start to deteriorate as early as 6 hours after production. Crumb rubber is prone to degradation (devulcanization and depolymerization) if its use is delayed thereby losing its vital properties such as elasticity and viscosity.

- Crumb rubber tends to separate and settle down in the bitumen. If some crumb rubber particles have settled to the bottom of the transport tanker or contractor's storage tank, the CRMB at the top may have quality, which is inferior to pure bitumen. This happens because the crumb rubber at the bottom has absorbed oils from the bitumen. In such cases, the CRMB actually used can be detrimental to the bituminous pavement. Therefore, after production CRMB should be agitated continuously through mechanical means during its transportation and its storage in contractor's bitumen tank. In India at present, there is not adequate infrastructure and quality control Programme in place for the effective use of CRMB.
- Selection criteria for viscosity grade bitumen are based on highest and lowest daily mean temperatures at a particular site.
- The Climate of Goalpara District is Warm and Temperate. The summer here have a good deal of Rainfall while winter have a very little rainfall. The Average Annual temperature in Goalpara District is 21.8° C. About 3200mm of Rainfall received by the District annually. The driest Month is December and most of the Rainfall receive is during the Month of June-July. August is the warmest month in the District. The temperature in August is 25°C - 26°C. January is the Coldest Month with average temperature is 15°C.
- East Garo Hills has the unique distinction of having the wettest place on earth i.e. Mawsynram with an average annual rainfall of about 12,270 mm. This is followed by Cherrapunjee with an average annual rainfall of 11,600 mm. Southwest monsoon originating from the Bay of Bengal and the Arabian Sea directly influences this high rainfall. The high-altitude areas of the district experience temperate humid climate and low altitude areas experience tropical to sub-tropical humid climate.
- The whole year can be divided into four seasons namely summer, rainy, autumn and winter. The temperature varies from 1.7 °C to 24 °C.
- Hence VG-40 grade of binder is recommended for DBM and BC as per Table-9.1 for Traffic level 20-50msa is VG-40 for BC & DBM.

7.0 TRAFFIC CONTROL AND SAFETY MEASURES

To enhance the safety of road user's adequate provisions for roadway width, geometric elements and junction improvements, have been proposed. In addition, due consideration has been given to the provisions contained in IRC: SP 44-1994, "Highway Safety Code". Various measures have also been proposed to enhance traffic control.

7.1 Road Signs

Adequate road signs have been proposed for the project road in order to provide advance information to guide, regulate / control traffic flow and ensure safe operations. Road signs will either be ground mounted or displayed as overhead gantry signs. The signs will be of retro-reflective sheeting of encapsulated type as per the MoRT&H specifications for Road and Bridge Works, 2001. Detailed drawings will be prepared for major intersections showing position and type of road sign. Road signs are to be installed at 2.0 m from the extreme edge of carriageway to ensure a safe clear zone and bottom edge of the lowest sign is not less than 1.5 m above the crown of the pavement. Ideally, in kerbed sections it is to be installed 60 cm away from the edge of the kerb and bottom edge of the lowest sign is not being less than 2.0 m above the kerb.

Generally, all signs are to be placed on the left side of the project road except at few locations where duplicate signs are to be placed on right side as well as signs related to traffic calming measures.

There are three categories of signs; Cautionary, mandatory and informatory signs. These would be provided depending on the situation and function they perform in accordance with the IRC: 67-2012 guidelines for Road Signs. The sign boards would be in accordance with specification of clause 801-3 of MORTH for high insensible sheeting. Overhead signs are proposed in accordance with IRC: 67-2012.

7.2 Road Markings

Road markings are provided to guide and assist the road users to negotiate conflict points and to be positioned at precisely the right location to make his maneuvers in the safest and quickest way so that the time vehicle's/ user's exposure to risk is minimized.

The markings serve as psychological barriers and signify the delineation of traffic paths and their lateral clearance from traffic hazards for safe movement of traffic. Road markings are therefore essential to ensure smooth and orderly flow of traffic and to promote road safety.

Pavement markings on the project road, location and type of marking lines, material and color have been proposed as per IRC: 35, "Code of Practice for Road Marking" with center-line, shyness and edge strip. The road markings would

be carefully planned on carriageways, intersections, bridge locations and built-up sections.

The pavement marking will be in thermo-plastic paint with glass beads as per the MORT&H specification for Road and Bridge Works, 2001. Detailed instruction has been provided in the drawings for major and minor intersections showing lane markings, pedestrian crossings, directional arrows etc.

7.3 Kilometer Stones

The details of kilometer and 5th Km stones would be in accordance with IRC: 8 guidelines. These are to be made of precast M-20 grade reinforced cement concrete, and lettering / numbering as per the respective IRC codes. Kilometer stones would be located on the left-hand side of the road as one proceeds from the station from which the Kilometer count starts. Kilometer stones would be fixed at right angles to the center line of the carriageway.

7.3.1 200m Stones and Boundary Stones

The details of 200m stones and boundary stones would conform to IRC: 26 and IRC:

25. 200m stones would be located on the same side of the road as the kilometer stones. The inscription on the stones would be the numerals 2, 4, 6 and 8 marked in an ascending order in the direction of increasing kilometer age away from the starting station. The numerals would be 80mm high. The color of the numerals would be black on a white background.

Boundary stones at 100 m interval staggered on each side and kilometer stone have been proposed as per the provision of IRC: 25-1967. In addition, these would be fixed at all angular points of the boundary. Where the boundary is on a curve or the land is of significant value and likely to be encroached upon, the boundary stones, as required, would be installed at closer intervals.

7.4 Delineators and Object Markers

Roadway delineators are intended to mark the edges of the roadway so as to guide drivers on the alignment ahead. Object markers are used to indicate hazards and obstructions within the vehicle flow path, for example, traffic islands close to the intersections.

Delineators and object markers would be provided in accordance with the provisions of IRC: 79. They are basically driving aids and would not be regarded as substitutes for warning signs, road markings or barriers. They are not provided at locations where Chevron sign boards are provided

Delineators provide visual assistance to drivers about the alignment of road ahead, particularly at right side. Three types of delineators have been proposed for the project roads as per the provision contained in IRC: 79 "Recommended Practice for Road Delineators", namely:

- Roadway indicators with rectangular retro-reflectorized chevron markers (80mm x 100mm) for all curves of radius 1000m or less, horizontal curves with deflection angle > 30° on plain / rolling terrain. Delineator plastic post of 1m long and 10 cm square section painted alternatively black and white in 15cm wide strips. Delineator posts are to be erected at the edge of the roadway. The overall line of posts should be parallel to center line of the road. These are to be placed at outer and inner side of curves with the spacing defined in IRC: 79 "Recommended Practice for Road Delineators".
- Striped retro-reflectorized hazard markers (30 cm x 90 cm) consisting of alternative black and yellow stripes sloping downwards at an angle of 45 degree towards the side of obstruction. These are to be erected immediately ahead of bridge railing/ crash barrier. The inside edge of markers is to be in line with the inner edge of the obstruction.
- Cluster of red reflectors arranged on triangular panel as object markers provided at the heads of medians and directional islands. The object markers are to be setback by 50 cm from the face of the Kerb. Height of the post will be 50 cm. Size of equilateral triangular panel will be 30 cm and there will be four red reflectors of 75 mm diameter. Triangular panel and post will be painted white.

7.5 Guard Post

Guard posts are proposed on the location where embankment height is in between 2.0 and 3.0m. The spacing of guard post would be 5.0m c/c in these areas. Typical Guard post consists of precast (M20) post of size 200mm x 200mm and a height of 600mm above ground level. They are encased in M15 cement concrete for a depth of 450mm below ground level. Guard posts are painted with alternate black and white reflective paint of 150mm wide bands.

7.6 Solar Road Stud (SRS)

Solar Road Stud (SRS) is an active Road Safety Device, which is anchored to the road surface alongside of centerline and edge line markings and delineation for nighttime visibility. It is a self-contained device with some Solar Module, Battery, LED and electronics, designed to switch - ON automatically at Dusk and flash throughout the night to provide adequate visibility and advance warning to the motorist while driving on the road. SRS works on Solar energy to operate LEDs that flash throughout the night, providing long range visibility, guidance and advance warning to road users, thus improving safety on roads. SRS are suggested at major intersections, built-up areas, curves with radii less than 100m.

7.7 Project Facilities

For efficient functioning and operation of road, user facilities such as bus bays, bus shelters and truck lay byes and traffic calming measures through built-up and activity areas are required to be paid adequate attention.

7.8 Bus Shelters

The project road is passing through a number of villages/towns. The bus shelters are proposed at these locations to provide user facilities and improve

safety of other users negotiating bus stop areas. Pedestrian crossing facility is also an integral part of bus stops to warn vehicle users and provide guided path for pedestrian to cross the highway. Total 2X4 bus shelters (Both Road) have been proposed in this section of project road.

Table 7.1: Locations for Bus shelter

S. No.	Design Chainage		Location
	Left	Right	
1	0+040	0+060	Dudhnoi
2	4+950	5+110	Near School
3	5+750	5+850	Damra
4	8+250	8+300	Daindubi

7.9 Truck Lay Bye

Truck lay bye has been proposed at 1X2 (In staggeed) location. List of locations is given in table below:

Table 7.2: Locations of Truck Lay Bye

Part-II

Design of Bridges & Culverts

8 CROSS-DRAINAGE STRUCTURES - MAJOR AND MINOR BRIDGES

8.1 Design Standards for Bridges/Structures

The design standards and loading considered for culverts and bridges are those laid down from the latest IRC codes. Where the said codes are silent other codes at national or international level shall be followed in consultation with the client.

- The Indian Road Congress (IRC) codes will be the basis of bridge designs, underpasses and flyover/ROB"s. For items not covered by latter, provisions of Special Publications and Specification for Roads and Bridges published by IRC shall be followed.
- Since number of new bridges in the project roads is less and majority of existing structures will be widened, it is proposed to design structures with working stress method based on IRC: 112.
- Grades of Concrete for superstructures will be as per MOST Specifications and IRC Standards. The Minimum grade shall be M40 for PSC and M25 for RCC respectively.
- For substructures and foundations, the concrete grade will not be lower than M25. For PCC substructures minimum grade of M20 will be adopted.
- The deck will have 2.5% unidirectional camber/cross fall and the wearing course will be of uniform thickness of 50mm BC laid over 12mm thick Mastic asphalt on all bridge decks.
- In general, it has been observed during the preliminary study that the open type foundations for the existing bridges have not suffered any distress.
- Pile / well foundations will be adopted for some of the Major bridges wherever open foundation is not feasible, depending on the properties of the foundation strata based on sub-soil investigation reports.

Table 8.1: Proposal of Major and Minor Bridges

Bridges

(a) Existing bridges to be re-constructed/widened

(i) The existing bridges at the following locations shall be re-constructed:

Sl. No.	Bridge location (Ch)	Existing Span Arrangement (m)	Existing Width (m)	Proposed Span Arrangement (m)	Proposed Width (m)	Remarks
1	4+150	1 x 25.00	8.40	1 x 25.00	16.00	Reconstruction
2	6+805	3 x 9.00	8.00	3 x 9.00	8.00	Widening

(b) New bridges

Note: Proposed span arrangement is minimum and any increase in length/span/height shall not be treated as change in scope of work.

IRC Class Special Vehicle loading shall be considered in the structural design of bridges/Flyover/VUP.

8.2 Design of Structures

Type of Structures

The structures are classified based on their functional use. The structures for the project road are classified as given below:

i) Drainage Structures

- Major Bridges
- Minor Bridges

• Culverts

Sl. No.	Design Chainage	Type of Structure	Proposed Span Arrangement (m)	Proposed width (m)	Remarks
1	0+800	Box Culvert	1 x 2	12.0	Reconstruction
2	2+345	Box Culvert	1 x 2	12.0	Reconstruction
3	3+385	Box Culvert	1 x 2	12.0	Reconstruction
4	5+515	Box Culvert	1 x 2	12.0	Reconstruction
5	5+915	Box Culvert	1 x 6	12.0	Reconstruction
6	6+305	Box Culvert	1 x 3	12.0	Reconstruction
7	6+445	Box Culvert	1 x 2	12.0	Reconstruction
8	7+110	Box Culvert	1 x 2	16.0	Reconstruction
9	8+410	Box Culvert	1 x 2	12.0	Reconstruction

ii) Viaducts

iii Grade Separators

- Overpasses
- Road/Rail over Bridges
- Underpasses

The Bridges having an overall length varying from 6 m to 60 m are termed as minor bridges and those having an overall length more than 60 m are termed as major bridges.

The structures carrying the project road over land and spanning across the valleys are termed as viaducts. The structures carrying the cross roads above the project road are termed as overpasses and the structures carrying the cross roads below the project road are called underpasses. Box type structures are generally proposed at important village road crossings.

Design Loading

The bridges have been designed to sustain safely the most critical combination of various loads, forces and stresses that can co-exist as per the provisions of IRC: 6-2014. The allowable stresses and the permissible increase in stresses for various load combinations have been adopted as per the relevant IRC codes.

Carriageway Live Load

Structures carrying the proposed project road with carriageway width of 11.0 m are proposed to be designed for 3 lanes of Class-A loading or one lane of 70-R wheeled/tracked loading plus 1 lane of Class - A loading, whichever produces the most severe effect.

Structures carrying the proposed project road with carriageway width of 7.5 m shall be designed for 2 lanes of Class-A loading or one lane of 70-R wheeled/tracked loading whichever produces the most severe effect.

Tractive and Braking Force

The tractive and braking forces shall be considered as per the provisions of clause no. 211 of IRC:6-2017.

Footpath Live Load

The footpath live load shall be considered as per the provisions of clause no. 209 of the IRC: 6-2017. The intensity of the footpath loading has been considered as 500 Kg/sqm as per clause no.206 of IRC: 6-2017.

Wind Forces.

The effect of wind as per clause no. 212 of IRC: 6-2017 shall be considered for the design of the various components of the bridge.

Seismic Forces

Project roads pass through seismic zone II, III and IV. Seismic forces shall be calculated in accordance with clause number 222.5 of IRC: 6-2017.

Buoyancy Effects

The following buoyancy effects shall be considered wherever applicable for the design of various components of the bridge:

For Foundations 100 %

For Substructure below water 15 %

Deck Levels of Structures

The deck levels of the structures carrying the project road have been adopted based on the following parameters:

- Vertical clearance required above the cross roads;
- Vertical profile of the proposed project road;
- Vertical clearance required above the high flood level

8.3 Hydraulic and Hydrological Investigations and Methodology

The project roads pass through areas of heavy intensity rainfall. Detail hydrological investigations have been carried out to confirm the adequacy of existing structures and requirement of additional culverts.

i) Collection of Data and Design Assumptions

The hydraulic condition of each structure was assessed thoroughly by visual observations. These observations were supplemented with local inquiries.

ii) Return Period and Rainfall

As per IRC: 5 - 2015 (Standard Specifications and Code of Practice for Road Bridges, Section I - General Features of Design (Eighth Revision)) the bridges are designed for a period of not less than 50 years. A flood of this specified return period should pass easily through the structure, while an extraordinary and rare flood may pass without doing excessive damage to the structure or the road.

Topographic maps, obtained from Survey of India, on 1: 50,000 scales, have been utilized for the hydrological study of the corridor.

iii) Cross-Sections and Longitudinal Section at Bridges

For the calculation of discharge of the stream by Area-Velocity method, topographical survey including levelling surveys have been carried out across and along the watercourses to determine the cross-section and the longitudinal section of stream. A number of cross-sections have been taken at regular intervals on both upstream and downstream side of the structure, including one at the proposed location of the structure in accordance with IRC specifications.

The following assumptions shall be made during peak discharge calculation:

For bridges where the cross section is not defined, the cross-sections shall be extended up to the HFL, in order to calculate the effective cross-section of flow.

The longitudinal section to determine the bed slope shall be taken at an approximate regular interval following the channel course extending on both the upstream and the downstream sides of the structure. Caution shall be exercised by following the curved flow line for longitudinal gradient, rather than a straight line.

Hydrology and Hydraulics of the Cross-Drainage Structures

Assessment of Peak Discharge

The peak discharge and the HFL shall be calculated by following methods

- Empirical Method
- Area Velocity Method
- SUH Method

Empirical Method

Inglis's Formula which is as under as per IRC SP-13.

$$Q = \frac{125 M}{(M + 10)^{1/2}}$$

Where,

Q = Peak run-off
(cumec)

M = Catchment area (sq km)

Dickens Formula which is as under as per IRC SP-13.

$$Q = C M^{3/4}$$

Where,

Q = Peak run-off (cumec)

M = Catchment area (sq km)

C = Coefficient of run-off, depends upon annual rainfall

The catchment area M is determined from toposheets, Coefficient of run-off C is determined from IRC SP-13 depending upon the intensity of rainfall. This formula gives a simplified approach and results are approximate. Comparison is made with alternative methods for important structures.

Ryve's formula which is as under as per IRC SP-13.

$$Q = CM^{2/3}$$

Where,

Q = Peak run-off (cumec)

M = Catchment area (sq km)

C = Coefficient of run-off, depends upon annual rainfall

The catchment area M is determined from the toposheets, Coefficient of run-off C is determined from IRC SP-13 depending upon the intensity of rainfall. This formula gives a simplified approach and results are approximate. Comparison is made with alternative methods for important structures.

Area - Velocity Method (Manning's Formula)

In this method, discharge is calculated using the formula given below

$$Q = A \times V$$

$$= A \times [(1/n) \times (R)^{2/3} \times (S)^{1/2}]$$

Where

Q = Discharge (cumecs)

A = Area of the cross section (sq. m.)

V = Velocity in (m/sec)

R = Hydraulic mean depth (m); $R = A / P$

P = Wetted perimeter of the stream (m)

n = Bed slope of the stream

= Rugosity Co-efficient.

Synthetic Unit Hydrograph Method

This method is based on unit hydrograph principle, used when catchment area is greater than 10 sq miles. CWC has published Flood Estimation Reports for different zones for India. Comprehensive hydraulic analysis of various CD structures shall be carried out based on detailed topographical survey.

A detailed approach and equations of unit hydrograph has been given in the report “Estimation of Design Flood Peak, Mahanadi Sub-Zone- s-d published by CWC. In this method the design flood discharge has been calculated as per guidelines given in the report.

Design discharge has been taken as the maximum of the peak flood discharge by different methods provided it does not exceed the next highest discharge more than 50%. If it exceeds, it is restricted to that limit (As per Article 6.2.1 of IRC: SP: 13-2004).

Hydraulic Analysis for Design HFL

In hydraulic analysis, the Design HFL shall be calculated corresponding to the Design Discharge by Manning’s Equation at the bridge site, as described above.

Afflux Calculation

When the waterway area of the opening of a bridge is less than the unobstructed natural waterway area of the stream, i.e., when bridge contracts the stream, afflux occurs. The afflux will

$$h = \frac{Q^2 V}{17.88 A^2 a} = 0.01524 \frac{Q^2 V}{A^2 a}$$

be calculated using Moles worth formula as given below:

Where,

- h = afflux (meters)
- V = average velocity of water in the river prior to construction (m/sec)
- A = Unobstructed sectional area of the river at proposed site (sq.m)
- a = Constricted area of the river at the bridge (sq.m)

Scour Depth

Lacey’s equation is adopted for estimating normal scour depth as per IRC: 5

$$d_{sm} = 1.34 (D_b^2 / K_{sf})^{1/3}$$

Where R is the Lacey’s regime scour depth, measured below HFL, q is the design discharge

intensity under bridge in cumecs per meter and f is silt factor

$$\text{given by the equation } K_{sf} = 1.76 (d_m)^{1/2}$$

Where d_{50} is the mean sediment size in mm. Normal scour depth based on Lacey's equation and the actual observed depth (equal to the difference between HFL and LBL)/1.27 are compared as per code. Higher of the two values is adopted for design. Silt factor „f“ is found from Lacey's equation corresponding to d_{50} size of bed materials. Maximum scour level for pier and abutment are calculated using a factor of safety of 2 and 1.27 respectively as per IRC: Code-5. For computing scour depth, design discharge is enhanced by 30% to provide for adequate margin of safety as per provision of IRC: 78 - 2014.

Determination of Waterway for a New bridge

When a new bridge is to be constructed, a designer has all the freedom to provide waterway as required. As per IRC-5:2015 clause 106.5.1, waterway (W) should be equal to Lacey's regime waterway (P) given by the equation:

$$P = W = C (Q^{1/2})$$

Where,

Q = design flood discharge in m^3/s

P = Wetted perimeter in meters

W = Linear waterway in meters (for wide river W is almost equal to P)

C = a constant usually taken as 4.8 for regime channels but it may vary from 4.5 to 6.3 according to local conditions.

The code also stipulates that the waterway so found should also be compared with linear waterway at HFL corresponding to design flood discharge and the minimum of the two should be adopted as the clear waterway under the bridge.

- Hydraulics Calculation is attached in Annexure-IX.

8.4 Design Methodology Minor Bridges (New)

General - the following aspects shall be considered while planning for the new bridges and structures:

- Proper sitting of bridge and geometrics of approaches;
- Linear waterways and minimum vertical clearances;
- Satisfactory geological conditions;
- Minimum distance from the existing structure consistent with construction requirements and hydraulic consideration;
- Modular approach in design for both superstructure and substructures;
- Minimum vertical clearance above design HFL

Deck Width - Overall deck width of structures is 16m.

Proposals - The proposals for minor bridges are based on the following considerations:

- Total deck width of the new minor bridges shall be 16m. with crash barrier on both sides.
- The new bridges are proposed to be designed for 4 - lanes of traffic.
- In order to reduce the number of expansion joints for improving the riding quality and for providing unobstructed flow under the bridges, the small multiple spans are proposed to be replaced with equivalent single spans wherever possible, matching with the existing opening.
- The new bridges will be on the same location to as existing ones.
- For bridges with RCC solid slab superstructures, tar paper bearings will be proposed and for bridges with PSC / RCC T-Beam and slab superstructures Pot cum PTFE / elastomeric bearings will be proposed based on design requirements.
- Strip seal expansion joints will be proposed for bridges with RCC T-beam and slab superstructure. For bridges with RCC solid slab superstructure filler type expansion joints are proposed.
- Foundations for the proposed structures will be same as those of existing bridges.
- Bed protection works will be provided for bridges with box cell structures.
- Splayed wing walls shall be provided for new / widened side of minor bridges.

Existing Bridges (Rehabilitation)

Deck Width - The existing two lanes minor and major bridges in good condition having deck width > 10 m are proposed to be retained with repairs and will not be widened under this project. For structures having deck width less than 10 m, the proposals will be as under:

a. Slab Bridges with open foundations:

Existing slab bridges in good condition are proposed to be widened to 16.0 m deck width by integrating existing and widened part. Symmetrical widening shall be proposed in general.

b. Arch Bridges with open foundations:

Existing arch bridges in good condition are proposed to be widened to 16.0 m deck width by adding a new structure along existing arch bridge [Asymmetrical widening] to get 16.0 m deck width.

Foundation details of arch bridges are not known except of few cases where well foundations are visible.

In case, arch bridge is found to be supported on well foundations during construction stage, widening proposal will require to be changed to new 2 Lane Bridge.

c. RCC/PSC/ Steel composite Bridges with open foundations:

- i. Existing structures in good condition having carriageway width ≥ 7.5 m are proposed to be retained with repairs.
- ii. Existing structures having carriageway width significantly less than 7.5 m are proposed to be replaced with new 2 Lane Bridge.
- iii. Decision for existing structures in good condition having carriageway width marginally less than 7.5 m regarding retaining them with repairs

/ replaced with new 2 Lane Bridge will be taken on case-to-case basis in consultation with Client.

d. RCC/PSC/ Steel composite/Arch Bridges with well foundations:

- i. Existing structures in good condition having carriageway width ≥ 7.5 m are proposed to be retained with repairs.
 - ii. Existing structures having carriageway width significantly less than 7.5 m are proposed to be replaced with new 2 Lane Bridge.
 - iii. Decision for existing structures in good condition having carriageway width marginally less than 7.5 m regarding retaining them with repairs / replaced with new 2 Lane Bridge will be taken on case-to-case basis in consultation with Client.
- e. Existing bridges having poor structural condition, hydraulic deficiency [Overtopping, excessive scouring] or falling under realignment of road geometry are proposed to be replaced by new 2-lane bridge having 12 m deck width.

8.5 Design Methodology Minor Bridges (Reconstruction)

EXCAVATION FOR OPEN FOUNDATIONS

SCOPE

The method statement outlines the procedure to be complied with for the excavation of open foundations.

CONSTRUCTION PROCEDURE

4.1 Setting Out

- * The limit of excavation shall be set out true to fines, curves and slopes

4.2 Excavation

- Excavation shall be done as per the dimensions specified in the drawings.
- The sides of excavation shall be left plumb.

4.3 Dewatering and protection

- Water met with in excavation shall be removed by pumping.
- Foundation trench shall always be kept dry
- Cofferdams of adequate depth and height shall be constructed to prevent the running water of river from entering foundation trench.

SAFETY

General Safety

The Site Managers will have overall responsibility for safety.

As the construction area will be generally isolated and with appropriate signs in place, the danger to injury of members of the general public is minimal. All site visitors within the areas will be accompanied by a member of the site team. The following general safety issues will be addressed on site Near towns, villages and all frequented places, trenches and foundation pits shall be

securely fenced, provided with proper caution signs and marked with red lights at night to avoid accidents. All adequate protective measures shall be taken to see that the excavation operations do not affect or damage adjoining structures.

Personnel and Safety

All new workers and staff will attend a Safety Induction Course before commencing of site work.

All personnel will wear safety helmets, safety boots and high visibility jackets. All unsafe acts or conditions are to be identified and corrected promptly or referred to the respective supervisor. Any accident or incident is to be reported immediately so that preventive action can be taken to prevent reoccurrence.

Training

All staff members will be briefed on the importance of monitoring on site safety by the Safety manager.

ENVIRONMENT

The Site Managers will have overall responsibility for the environment.

All new workers and staff will attend the Environmental Induction Course before commencing of site.

Typical environmental management measures will be monitored in accordance with the following documents.

The Project Environmental Plan, The Project Management plan.

8.6 Design Methodology Minor Bridges (rehabilitation if any)

Proposals - The following measures are proposed for rehabilitation of existing bridges:

General Most of the bridges have many common deficiencies/defects, which are proposed for repaired as follows:

- 1) Railings / handrails are proposed be replaced with crash barriers to bring common bridge furniture across the project road. Keying of concrete crash barrier with brick work walls shall be done in addition to anchoring crash barrier reinforcement into brickwork by drilling holes and grouting with cement mortar.
- 2) Drainage spouts provided in the railing kerb, ending at face of soffit of slab are proposed be replaced with new drainage spouts having adequate length to prevent the water from falling / splashing on the superstructure.
- 3) Damaged faces of RCC pier caps/abutment caps over brick masonry (BM) / coursed rubble masonry (CRM) substructure shall be repaired by guiniting after removing the affected portions.
- 4) Damaged pointing in the BM / CRM to be removed and cleaned before applying fresh pointing.
- 5) Cracks in BM /CRM abutments/wing walls/piers shall be pressure grouted with cement grout through holes drilled in the masonry around the cracks.

- 6) Most of the existing bridges do not have approach slabs. Provision of approach slab is proposed to be made by reconstructing dirt wall with bracket to support approach slab for structures with RCC dirt walls. For structures PCC dirt walls, approach slab will not be provided in existing and widened part.
- 7) Stone pitching on earth fill around abutment has not been provided, except in 2-3 cases, resulting in settlement of earth fill exposing cantilever return walls, erosion of soil around return walls and in front of the spill through abutments. This can cause settlement of approach road behind abutments any time and block movement of traffic. This can cause traffic accidents also as parts of embankment can settle during rains.
- 8) Concrete wearing coat provided in number of bridges has suffered cracks and distress at number of locations. Reinforcement has come out in many distressed locations. Concrete wearing coat shall be replaced with bituminous wearing coat.

Solid Slab Superstructure

- 1) Edges of solid slab which show spilling of concrete over a smaller width or only small patches of the underside of slab which are distressed, are proposed to be repaired by guiniting. The reinforcement, which has corroded, shall be sand ballasted and additional reinforcement, if required, shall be welded to the existing reinforcement before guiniting.
- 2) RCC solid slabs, which show honeycombing, shall be strengthened by pressure grouting with cement grout from the underside of the slab.

T-Beam and Slab Superstructure

- 1) No such structure is found on the project stretch

8.7 Bridges on various Roads

The list of minor bridges is given in previous sections for the project roads. The existing bridge is multi span bridges of span less than 10m. The span of the bridges ranges from 5m to 10m. Overall width of the structure is also varying from 7m to 11m.

The existing bridges are generally of solid slab type super structure, resting on PCC/RCC/Stone Masonry type of sub structure. The foundation type is also visible at few locations and generally the foundation is open foundation or raft foundation.

Condition of bridge constructed on RCC/PCC sub structure is generally fair. These bridges are relatively new bridges. The distress of super structure is clearly visible. Sub structure is also damaged and foundations are scoured.

Approach slabs are mostly not provided. Railing/Parapets are also broken. Condition of wing wall is also not good for most of the bridges.

Generally, the retained bridges which are in good condition need following repairs:

- Remove vegetation growth on structure.
 - Repair damaged return walls.
 - Clear the waterway.
 - Replace existing parapet with RCC crash barrier.
 - Replace damaged wearing coat.
 - Provide approach slab.
 - Repair for small damages in the structural components.
-
- Details of Culvert & Bridge Inventory attached in Annexure-III & IV respectively.
 - Details of Improvement Proposal of Structures attached in Annexure-V.

9 CROSS-DRAINAGE STRUCTURES - CULVERTS

9.1 Hydrology

According to IRC: SP:73-2018 Clause 7.7 Culvert and Bridge using Pipes.

Project Road should have adequate cross drainage facility as large number natural drains/outfalls are present in project road. Additional culverts are required to balance the flood water on both sides of embankment to reduce flood level on one side of road; To balance the discharge from road catchment area and discharge passing through new/existing cross drainage structures as localized natural drains are very less in the project area, Cross drainage structure density is low - in some locations there is no culvert in 1 km stretch

Intermediate culverts, also called balancing culverts, have been proposed to reduce the length and size of the roadside drain. Guidelines in IRC: SP: 42, IRC: SP: 13-2004 and relevant IRC have been followed for proposing the number of cross drainage structures.

9.2 Proposal for New Culverts

For culverts, following guidelines will be followed:

- For culverts in new carriageway, minimum span and vent height will be kept equal to that of those in the existing carriageway; raising of deck level according to highway alignment will be made wherever required
- Weak and non-functional culverts to be dismantled and new culverts to be constructed with deck level matching with highway plan and profile.
- For widening of culverts to required width, existing Brickwork / RR masonry / PCC abutments will be widened on both sides of the existing culverts. Existing slab shall be widened with specified camber to be cast for the full length
- In case of culverts whose bed and floor have scoured off severely and considerable afflux is observed, the same will be replaced with new culverts having adequate vents or with a minor bridge, based on hydrological studies
- Culverts will be designed for IRC Class-A/Class-70R Tracked/Class-70R Wheeled Loading as per relevant IRC provisions
- Culverts shall be constructed for full formation width of the roadway
- All new pipe culverts shall be of minimum 1.2 m diameter.

9.3 Improvement Proposals

9.3.1 Culverts

Hume pipe culverts are proposed for reconstruction in NP4 RCC Pipes in full formation width including parapets, as per type design requirements laid down in IRC: SP:13. These culverts have been proposed in such stretches where required minimum cushion over the pipe is available. The bedding for pipe shall be first class bedding, comprising of granular material for culverts with cushion above the pipe not less than 0.6 m and not exceeding 4 m. details of improvements proposal are culvert.

Table 9.1: New Culverts

Culverts shall be provided at the following locations:

Sr. No.	Design Chainage	Proposed Type of Culvert	Proposed Span Arrangement (m)	Proposed Overall Width (m)	Remarks
<i>Nil</i>					

- a. Over all width of all culverts shall be equal to roadway width of the approaches.

10 PROTECTION WORKS & DRAIN

10.1 Retaining wall

Reinforced earth wall has been proposed at high embankment locations. Details are tabulated below.

Table 10.1: Details of Retaining Wall

FLEXIBLE PAVEMENT DESIGN IRC:37-2018**Dudhnoi to Dainadubi Road****Estimation of effective subgrade modulus/CBR :-**

Subgrade 90th percentile CBR = 5.375 %
 Borrow Area CBR = 8.62 %

Elastic modulus of the prepared (upper 500 mm)
 embankment soil = $17.6 * (CBR)^{0.64}$ Eq. 6.2 of IRC-37-2018
 = 51.64 Mpa

Elastic modulus of the selected borrow area
 material = $17.6 * (CBR)^{0.64}$ Eq. 6.2 of IRC-37-2018
 = 69.86 Mpa

Consider the poisson's ratio value of both the layers to be = 0.35

Single load= 40000 N

Contact Pressure= 0.56 Mpa

Radius of circular contact area for this load and contact pressure = 150.8 mm

From input data, Surface deflection (From IITPAVE) = 2.256 mm (IITPAVE Results attached)

Foe an equivalent single layer system, the modulus value of the single layer which will produce the same surface deflection of 2.256 mm for the same load and for a poisson's ratio of 0.35

$$M_{RS} = \frac{2(1-\mu^2)pa}{\delta} \quad \text{Eq. 6.3 of IRC-37-2018}$$

$$M_{RS} = 65.694 \text{ Mpa}$$

Using eq. 6.2 The corresponding CBR= 7.83 %

The effective CBR is 7.83 % of the subgrade has been determined as per clause 6.4 of IRC 37-2018.

Further, 7% effective CBR is adopted for the Pavement Design Purpose.

FLEXIBLE PAVEMENT DESIGN IRC:37-2018**Dudhnoi to Dainadubi Road**

Effective CBR =	7	%
Thickness of Granular layer =	150	mm
μ bituminous =	0.35	
μ granular =	0.35	
$\mu_{ctb/ctsb}$ =	0.25	
Design MSA (Bituminous) =	20	
Design MSA (CT base / granular) =	20	
Reliability =	90	%

Assumed Thickness (mm)	
BC	30
DBM	50
WMM	150
CT sub base	200
	430

Resilient Modulus (M_{RS}) of Sub-grade :-

$$M_{RS} = 10.0 \times \text{CBR} \quad \text{For CBR upto 5\%}$$

$$M_{RS} = 17.6 \times (\text{CBR})^{0.64} \quad \text{For CBR > 5\%}$$

As per IRC:37-2018, Clause 6.3 of page no. 20

$$M_{RS} = 61.15 \text{ Mpa}$$

$$E_{WMM} = 350.00 \text{ Mpa}$$

Elastic modulus of cemented layer :

As per IRC:37-2018, Table 11.1, page no. 36

$$E_{CTSB} = 600 \text{ Mpa}$$

**Fatigue cracking criteria for bituminous layer i.e.,****Allowable tensile strain at the bottom of the bituminous layer :-**

$$N_f = 0.5161 \times C \times 10^{-04} [1/\epsilon_t]^{3.89} [1/M_{Rm}]^{0.854}$$

Where,

(for 90% reliability from equation 3.4, page no. 6 IRC:37-2018)

$$C = 10^M, \text{ and } M = 4.84 \times [V_{be}/(V_a + V_{be}) - 0.69]$$

$$N_f = 20 \text{ Msa} = 20 \times 10^6$$

$$M_{Rm} = 3000$$

$$\text{Volume of Bitumen } V_{be} = 11.5 \%$$

$$\text{Volume of Airvoids } V_a = 3.5 \%$$

(Clause 12.3, page no. 35 of IRC:37-2018)

$$M = 0.371066667$$

$$C = 2.349993531$$

$$\epsilon_t = 0.0002028 \text{ (By IITPave)}$$

$$20 \times 10^6 = 0.5161 \times 2.35 \times 10^{-4} \times (1/\epsilon_t)^{3.89} \times (1/3000)^{0.854}$$

$$20 \times 10^6 = 0.000121283 \times (1/\epsilon_t)^{3.89} \times 0.001072849$$

$$(1/\epsilon_t)^{3.89} = \frac{20000000}{0.000121283 \times 0.001072849}$$

$$(1/\epsilon_t)^{3.89} = 1.53706 \times 10^{14}$$

$$(1/\epsilon_t) = 4435.721521$$

$$\epsilon_t = 0.000225442$$

Hence the Pavement Composition on Bituminous Layer is

SAFE

Subgrade Rutting criteria i.e.,

Allowable verticle compressive strain on the top of the Subgrade :-

$$N_R = 1.41 \times 10^{-08} [1/\epsilon_v]^{4.5337}$$

(for 90% reliabilty from equation 3.2, page no. 5 IRC:37-2018)

$$20 \times 10^6 = 1.41 \times 10^{-08} [1/\epsilon_v]^{4.5337}$$

$$[1/\epsilon_v]^{4.5337} = \frac{20000000}{1.41 \times 10^{-08}}$$

$$[1/\epsilon_v]^{4.5337} = 1.41844 \times 10^{15}$$

$$1/\epsilon_v = 2198.066929$$

$$\epsilon_v = 0.000454945$$

$$\epsilon_v = 0.0004059 \text{ (By IITPave)}$$

Hence the Pavement Composition on Subgrade is

SAFE

HOURLY ABSTRACT OF CLASSIFIED TRAFFIC VOLUME COUNT SURVEY (UP)

Road : Dudhnoi - Dainadubi (8.6 km)

Road No. : 1

Direction : Dudhnoi - Dainadubi

Station No. : 1

Location : At km 3+500 (Near Damra A.S.A. Playground)□

Date & Day : Sunday, November 18, 2018

Addl. Information: 0

Hour : 8 AM to 8 AM

Weather: Normal

$$N = \frac{365 \times [(1 + r)^n - 1]}{r} \times A \times D \times F$$

For 20 Year N= 3.14 MSA
For 30 Year N= 6.31 MSA

N = MSA
r = Traffic Growth Rate
n = Design Year
D = Lane Distribution Factor
F = VDF
A = No of Commercial Vehicles at the start of projection

**Name of Project :- Consultancy Services For Development Of Economic Corridors, Inter Corridors
And Feeder Routes To Improve The Efficiency Of Freight Movement In India Under Bharatmala
Pariyogana Lot-1 (Ii. Dhudnoi to Dainadubi)**

Sr. No.	Existing Chainage	Design Chainage	Type of Proposal	Type of Structure	Span Arrangement (m)	Overall Width (m)	CA (km ²)
1	4+150	4+150	Reconstruction	Minor Bridge	1x25	16.00	1.70

**Name of Project :- Consultancy Services For Development Of Economic Corridors, Inter Corridors
And Feeder Routes To Improve The Efficiency Of Freight Movement In India Under Bharatmala
Pariyogana Lot-1 (li. Dhudnoi to Dainadubi)**

Hydraulic Calculation of Minor Bridge at Chainage 4+150 M.

1. Introduction:

The length of a bridge, depth of foundation & formational level are dependent on the maximum recorded quantum of water or flood discharge which has passed through the river or the channel over which the bridge is proposed and as such the design discharge is very important not only from economic consideration but also from safety or stability consideration. Therefore, the design discharge, which might be the recorded discharge during the past 50-100 years, shall be ascertained very carefully.

The following methods are used for the estimation of flood discharge:

1. Peak Run-off from catchment by using Empirical Formulae.
2. Peak Run-off from catchment and other characteristics of rainfall by using Rational Method.
3. Flood discharge from Cross-Sectional Area-Velocity Method as observed on the stream at the bridge site.

2. Codes Referred for Design Purpose:

IRC: 5 - 2015	Standard Specifications and Code of Practice for Road Bridges
	Section - I, General Features of Design
IRC: SP: 13 - 2004	Guidelines for the design of small bridges & culverts

3. Abstract of Hydraulic Calculation:

Catchment Area	=	1.697 Sq.km.
Design Discharge	=	49.07 m ³ /s
Required Linear Waterway	=	33.62 m
Provided Effective Linear Waterway	=	23.64 m
Design Velocity	=	4.31 m/s
Lowest Bed Level	=	61.027 M
Max. Scour Level	=	61.027 M
Highest Flood Level (Observed)	=	65.564 M
Highest Flood Level (Designed)	=	65.714 M
Formation Level	=	68.814 M

Hydraulic Calculation of Minor Bridge at Chainage 4+150 M. Annexure-VII

4. Dickens Formula to Calculate Peak Run-off from Catchment:

Area of Catchment	A	=	169.70 Ha
Dickens Constant	C_D^*	=	22
Discharge	$C_D \times (A)^{3/4}$	=	32.71 m ³ /s

5. Rational Formula to Calculate Peak Run-off from Catchment:

Area of Catchment	A	=	169.70 Ha
Length of Longest Stream	L	=	12.44 km
The Fall in Level between source and site	H	=	134.78 m
Co-efficient of Runoff <i>(Refer IRC:SP:13-2004, Table 4.1)</i>	P	=	0.80
100 Years - 24 Hour Rainfall <i>(Refer Plate-10 of subzone 2(b))</i>		=	40.00 cm
100 Years - 1 Hour Rainfall <i>(39% of 24 Hour Rainfall)</i>	I_o	=	15.60 cm
Mean Intensity fraction <i>(Refer IRC:SP:13-2004, Fig. 4.2)</i>	f	=	0.99
Concentration time	$t_c = (0.87 \times L^3 / H)^{0.385}$	=	2.64 hrs.
Critical Intensity of Rainfall	$I_c = I_o (2 / t_c + 1)$	=	8.58 cm/hr
Discharge	$0.028 P f A I_c$	=	32.28 m ³ /s

Hydraulic Calculation of Minor Bridge at Chainage 4+150 M. Annexure-VII

6. Cross-Sectional Area-Velocity Method to Calculate Flood Discharge:

Since the bridge is provided across a defined stream, we estimate flood discharge from the conveyance factor & slope of the

From the survey data & local enquiry, we fix the observed H.F.L. = 65.564 M

15.00	65.564						
Average =		63.268		3.576	Total =	27.82	80.41

Discharge Calculation by Area Velocity method (Using Mannings formula)

Hydraulic Radius	$R = A / P$	=	2.89
Slope of River Bed	S	=	0.0055
Rugosity Co-efficient	n	=	0.035
Therefore, Velocity	$V = R^{2/3} \times S^{1/2} / n$	=	4.31 m/sec
and Discharge	$Q = A \times V$	=	346.78 m ³ /s

Hydraulic Calculation of Minor Bridge at Chainage 4+150 M. Annexure-VII

7. Linear Waterway Calculation:

Discharge Calculated by Dicken's Formula	=	32.71 m ³ /s
Discharge Calculated by Rational Formula Formula	=	32.28 m ³ /s
Discharge Calculated by Cross-Sectional Area-Velocity Method	=	346.78 m ³ /s

As per IRC:SP:13-2004, Clause 6.2.1*, Design Discharge (Q) = **49.07 m³/s**

*The highest of these values should be adopted as the design discharge Q, provided it does not exceed the next highest

As per Design Discharge, Linear Water Way Required	(4.8 x \sqrt{Q})	=	33.62 m
Bank to bank distance		=	30.00 m

Considering all the above parameters, We are proposing a High Level Bridge, details of which are given below:

Type of Bridge	:	R.C.C. Solid slab	
Span Arrangement			= 1 Span(s) of 25 m.
No. of Spans			= 1
Overall Span Length			= 25.00 m
Bearing Center to Deck End			= 0.40 m
Effective Span (center to center of bearings)			= 24.20 m
Total Bridge Length (between inner faces of dirt wall)			= 25.00 m
No. of Expansion Gap at bridge portion			= 2
Expansion Gap between two adjacent span			= 0.02 m
Total Bridge Length (i/c Expansion Gap)			= 25.04 m
No. of Piers			= 0
Thickness of One Pier			= 1.00 m
No. of Abutments			= 2
Distance from dirt wall inner face to Abutment inner face			= 0.70 m
Total Obstruction caused due to Sub-Structure			= 1.40 m
Provided Effective Linear Waterway			= 23.64 m
Clear Vertical Height			= 7.19 m
Provided Area of Opening			= 169.90 m²
Velocity of Stream			= 4.31 m/sec
Quantum of Discharge which can be passed through Provided Opening			= 732.71 m³/s
			Hence Safe
Required Linear Waterway			= 33.62 m
Percentage of Obstruction caused due to Sub-Structure			= 6.42 %

Here the obstruction caused by sub-structure is 6.42%. However, the obstruction caused to the discharge by the approach roads and bridge structure itself should not be more than 30%. Hence, the proposed linear waterway is in order.

Hydraulic Calculation of Minor Bridge at Chainage 4+150 M. Annexure-VII

8. Fixation of Formation Level:

Highest Flood Level (H.F.L.)	=	65.564 M
Afflux	=	0.150 m
Designed Highest Flood Level (De. H.F.L.)	=	65.714 M
Vertical Clearance *	(Refer IRC:SP:13-2004, Table 12.1)	= 2.500 m
Soffit Level	(De. H.F.L. + Afflux + Vertical Clearance)	= 68.214 M
Depth of Top Slab+Girder	=	0.550 m
Wearing Course on Deck Slab	=	0.050 m
Formation Level as per hydraulic	(Soffit Level + Depth of S.S. + Wearing Course)	= 68.814 M
Formation Level due to Profile correction		69.060 m

* Note: Vertical Clearance is taken more than the value specified in IRC:SP:13-2004, Table 12.1 to match the deck level to the

Hydraulic Calculation of Minor Bridge at Chainage 4+150 M. Annexure-VII

9. Scour Depth Calculation :

Design Discharge	=	49.07 m ³ /s
%age Increment over Des. Discharge (Refer IRC:78-2014, Clause 703.1.1)	=	30 %
Incremented Design Discharge (for scour calculation only)	=	63.79 m ³ /s
Provided Effective Linear Waterway	=	23.64 m

Scour Depth Calculation :-

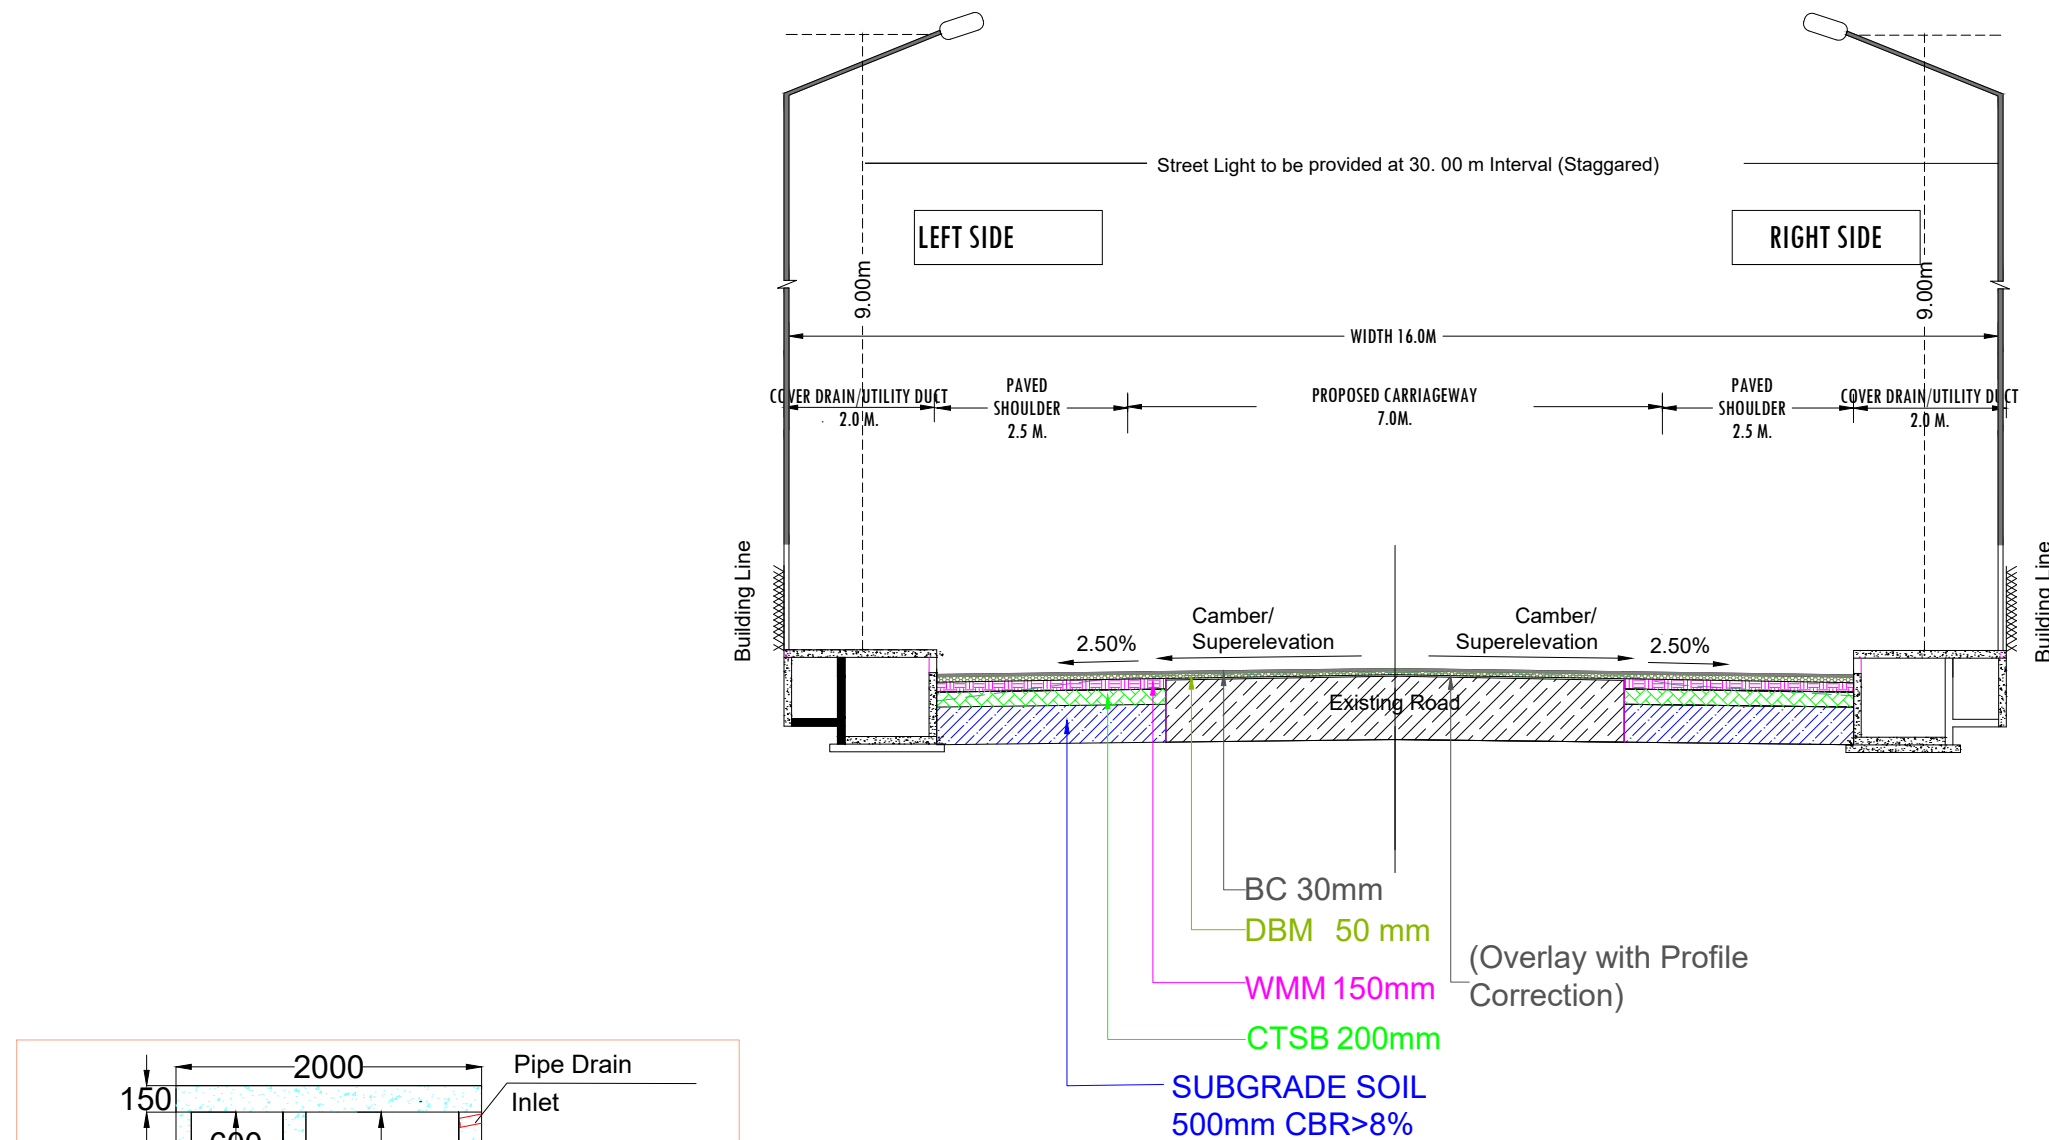

D_b = Inc. Design Discharge / Eff. Waterway	=	2.70 m ³ /sec/m
K_{sf} = Silt Factor (Refer IRC:78-2014, Clause 703.2.2.1)	=	1.75
d_{sm} = Mean Scour Depth (As per IRC:78-2014, Clause 703.2)		
$d_{sm} = 1.34 \times (D_b^2 / K_{sf})^{1/3}$	=	2.155 m
$d_{sm} = [(HFL - LBL) / 1.27 \text{ Criteria}]$	=	3.572 m
Mean Scour Depth (d_{sm}) (Max. of above two values)	=	3.572 m
Highest Flood Level (H.F.L.)	=	65.564 M
Normal Scour Level (H.F.L.- d_{sm})	=	61.992 M
Max. scour depth = (1.27 x d_{sm})	=	4.537 m
Max. Scour level *	=	61.027 M
Avg. Bed Level	=	63.268 M
Min. Foundation Level #	=	59.027 M
		or upto Rock Lvl

Note: Foundation levels are calculated on the basis of maximum scour level. Final foundation levels are subjected to availability of
